PHLEBOTOMUS (PAPPATASI) OR SANDFLY) FEVER

A DISEASE OF MILITARY IMPORTANCE

SUMMARY OF EXISTING KNOWLEDGE AND PRELIMINARY
REPORT OF ORIGINAL INVESTIGATIONS

MAJOR ALBERT B. SABIN

MEDICAL CORPS, ARMY OF THE UNITED STATES

LIEUTENANT COLONEL CORNELIUS B. PHILIP

SANITARY CORPS, ARMY OF THE UNITED STATES

AND

JOHN R. PAUL, M.D.

NEW HAVEN, CONN.

Phlebotomus fever, also commonly called pappatasi or sandfly fever, is a specific febrile disease of virus etiology which is of considerable military importance because of its occurrence in many parts of the world where troops are stationed. The adult native populations are for the most part immune, but when troops or other people from areas where the disease is not prevalent move into endemic zones they succumb in large numbers. While the disease is self limited and there are no fatalities, its military importance lies in the fact that it can incapacitate large numbers of men for periods of seven to fourteen days or longer at a time when their services may be needed most. The clinical picture of Phlebotomus fever resembles that of influenza but without the signs of acute inflammation of the respiratory tract which commonly accompany the latter disease. It is characterized by fever ranging from 100 to 105 F., severe headache, pain in the eyes, photophobia, subjective stiffness of the neck, pain in the back, muscles, bones and joints, associated on occasions with anorexia, nausea and vomiting, abdominal distress, and constipation or diarrhea. The fever usually lasts only about three days, although it may be shorter or longer, but convalescence is sometimes slow, weakness, dizziness, diarrhea and depression continuing for another ten days or longer, depending on the individual and the climate. In 1908 an Austrian

These investigations were carried out under the Commission of Neurotropic Virus Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Division, Office of the Surgeon General, United States Army. Part of the work was carried out in the Commission's Laboratory in the Middle East and the remainder at the Children's Hospital Research Foundation and the Longview State Hospital, Cincinnati.

The number of American and British officers and men who assisted us in this work is too great to allow individual mention here. In particular, however, we wish to include Col. C. F. Sains, M. C., Col. D. W. Billick, M. C., Col. H. C. Van Vlack, M. C., Lieut. Col. B. L. Keyes, M. C., Lieut. Col. F. Sewell, M. C., Lieut. Col. T. G. Ward, M. C., and Major C. S. Byron, M. C., of the U. S. Army Forces in the Middle East; Lieut. Col. A. A. Carabelli, M. C., of the Persian Gulf Service Command, and Col. D. Franklin, M. C., Lieutenant Colonel Norton and Major S. C. Wagoner, M. C., of the Seventh Army.

We are also indebted to Brig. Gen. G. X. Cheves, U. S. Army, for granting permission for us to carry out experiments designed to test the efficiency of insect repellents on American troops.

The following British officers also assisted us: Major C. R. Ames, R. A. M. C., Lieut. Col. J. B. Scott, R. A. M. C., and Lieutenant Colonel Elliot and Major E. D. Cooper of the South African Medical Corps.

military commission consisting of Doerr, Franz and Taussig¹ reproduced the disease in human beings by inoculation of blood obtained from patients on the first day of the fever and established the fact that the agent was filtrable and that the midges known as Phlebotomus papatasi² were vectors of the disease.

Phlebotomus fever appears to persist chiefly, although not exclusively, in the lowlands of those subtropical and tropical countries in which there are long periods of hot, dry weather. The disease is distinctly seasonal, the highest incidence occurring between the months of April and October in different parts of the world, depending on the prevailing temperatures and the periods when the rainy season ceases and reappears. Its widespread geographic distribution, particularly in those parts of Europe, Africa and Asia which lie in the belt between 20 and 45 degrees north latitude, has become apparent from reports dating from the beginning of the nineteenth century³ to the present day, in which the disease has been described under a variety of names including three day fever, Mediterranean dengue, summer influenza, summer fever, hundskrankheit, soldaten fieber, acclimatization fever, endemic or climatic gastroenteritis and chitral fever. The disease is definitely known to occur in Italy as far north as the Po valley, Sicily, along the Adriatic coast of Yugoslavia as far north as the Istrian peninsula, Greece, Malta, Crete, Cyprus, Egypt, Palestine, Syria, Iraq, Persia (Iran), Crimea and the Transcaucasian region, and the northwest and central provinces of India. There are also reports which would suggest that this disease may occur in China as far north as Peiping and Tientsin and as far south as Hongkong, in Burma along the coast of the Bay of Bengal, in Ceylon, in the Poona region of India, in Aden and along the adjacent Red Sea coast of Arabia, the Anglo-Egyptian Sudan, along the Mediterranean coast of Africa—particularly the eastern portion, Corsica, the Mediterranean coast of France, Gibraltar, and along the Atlantic coast of Portugal.⁴ Reports of a similar disease in countries lying just north or south of the equator have come from Kenya⁵ and the Tanganyika Territory in Africa⁶ and from the region of Bolivar in South America.⁷ The disease is not known to occur in the

1 Doerr, R.; Franz, K., and Taussig, S. Das Pappataciefieber, Leipzig, Franz Deuticke, 1909.

2 The term "papatasi" is used to designate the vector in accord with Scopoli's original spelling, while "pappatasi" was the name given to the disease by the Austrian commission because it was the popular name for these insects.

United States. Phlebotomus fever was one of the diseases investigated by a commission of which we were the members, which went to North Africa early in 1943. Clinical and laboratory studies were carried out on human volunteers from the ranks of the American armed forces in the commission's laboratory in the Middle East, and subsequently on larger numbers of human beings in the United States.⁸ Two strains of virus were isolated from the blood of patients—one strain from the Middle East and the other from Sicily. More than 100 cases of the experimental disease produced in human beings during the course of various experiments and tests have now been observed. Our purpose in the present communication is to report on the present status of our knowledge concerning the etiology, transmission, epidemiology, clinical manifestations, diagnosis, immunity and prophylaxis of Phlebotomus fever.

PROPERTIES OF THE ETIOLOGIC AGENT

The original studies of Doerr and his co-workers⁹ (later confirmed by others¹⁰) established that the serum obtained during the first twenty-four hours of the fever, but not at forty hours or later, contained an agent which could reproduce the disease in human beings, even after filtration through filters which prevented the passage of ordinary bacteria. Moshkovsky and his associates¹¹ demonstrated that the virus may be present in the blood one to two days before the onset of fever. Although many unsuccessful attempts had been made to transmit the disease to the usual laboratory animals, such studies were not extensive and on occasion were equivocal.

Our own investigations yielded the following information:

1. Serum obtained from spontaneous cases occurring in troops in the Middle East and Sicily regularly reproduced the disease in human volunteers.
2. In the experimentally reproduced disease the virus was found in the blood at least twenty-four hours before the onset of fever and during the first twenty-four hours of the fever but was no longer demonstrable forty-eight hours after onset.
3. The virus has been passed in series seven times by inoculation of serum from human being to human being without any apparent change in its properties.
4. By means of the intracutaneous or intravenous routes of inoculation, approximately 95 per cent of over 100 human adults were found to be susceptible regardless of sex or color.
5. Doses of virus (i. e. infected serum) which almost regularly produced the disease when inoculated intracutaneously or intravenously failed to produce the disease in 50 to 75 per cent of individuals in simultaneous tests when the inoculation was given subcutaneously or intramuscularly.

8. The studies in the United States also formed part of a fever therapy program for patients with dementia paralytica at the Longview State Hospital, Cincinnati. The cooperation of Dr. Douglas Goldman, medical director, and Dr. E. A. Baber, superintendent, of the institution made this work possible.

11. Moshkovsky, S. D., and others: Pappataci Fever, Med. Parasitol., Moscow 5: 823, 1936.

6. The largest amount of virus per cubic centimeter of serum obtained at the onset of fever was about 1,000 infective doses, but there is reason to believe that it may sometimes be less.

7. No virus was demonstrated in cerebrospinal fluid obtained on the first and second days of the experimentally reproduced disease even when large amounts (2 cc. intracutaneously and 15 cc. intravenously) of the cerebrospinal fluid were inoculated.

8. The virus was preserved for at least six months in the frozen state by storage at the low temperature produced by solid carbon dioxide or in the lyophilized state, stored in an ordinary refrigerator. Longer periods have not yet been tested.

9. Gradocol membrane filtration tests revealed that the virus is of small size. It passed with ease through all membranes having an average pore diameter of 200 millimicrons or more.¹² Passage through the 100 millimicron average pore diameter membrane is probable but questionable, since the filtrate did not reproduce the disease, although 2 of the 4 human subjects used in the test were immune to subsequent inoculation of active virus. Neither disease nor immunity followed the inoculation of filtrates from the 75 or 50 millimicron average pore diameter membranes. Applying Elford's formula to these data, one may say that the virus is certainly not larger than 40 to 60 millimicrons and quite probably not larger than 25 to 37 millimicrons. However, in view of the fact that the amount of virus in the serum used for filtration was only about 1,000 minimum lethal doses per cubic centimeter, it is not improbable that the true size of the Phlebotomus fever virus may be even smaller and perhaps fall in the same range of magnitude as that of yellow fever, which is 22 millimicrons.

10. The pathogenicity of the virus was tested by inoculation of serum or blood of proved infectivity for human beings by the intracerebral, intracutaneous, subcutaneous, intratesticular, intranasal or intraperitoneal routes in the following lower animals:

Young baboons (*Papio hamadryas*) and monkeys of the following species: grivet (*Cercopithecus griseoviridis*), vervet (*Cercopithecus aethiops centralis*), red African hussar (*Cercopithecus [Erythrocebus] patas*), *Macaca radiata* and *Macaca mulatta* (rhesus). The rodents included young white mice, wild gray mice, Syrian hamsters, Egyptian desert rats (jerboas), rabbits, guinea pigs and cotton rats.

No evidence of pathogenicity was obtained. The virus could not be demonstrated in the serum of 3 rhesus monkeys three and four days after inoculation, although the human beings in whom the tests were made developed transitory fever associated with serum sickness.

11. No evidence was found that the virus produced specific plaques on the chorioallantoic membrane of chick embryos,¹³ nor did it appear that the embryos

12. Dr. Johannes Bauer of the International Health Division of the Rockefeller Foundation supplied most of the gradocol membranes used in these tests.

were adversely affected when the inoculations were made into the embryo, allantois or yolk sac. Subinoculation of the third and fourth passage chick embryo cultures (propagated by the same technic used in growing yellow fever virus for vaccine production) into human beings did not reproduce the disease.

CAPACITY OF VARIOUS BLOODSUCKING INSECTS TO TRANSMIT THE DISEASE

The capacity of *Phlebotomus papatasi* caught in endemic zones, with or without previous known exposure to an infected individual, to transmit the disease to susceptible human beings was established by Doerr⁹ and extensively confirmed by others.¹⁴ The evidence is suggestive, although not entirely satisfactory, that approximately one week is required for the virus to develop in these insects before they are capable of transmitting the disease after an infectious blood meal. The bedbug is the only other bloodsucking insect that had been tested (Doerr¹) and it did not transmit the disease. Although other species of *Phlebotomus*, namely *pernicius*, *minutus*, *causasicus* and others, have been found in areas where the disease has occurred, there is as yet no experimental proof as to whether or not they may be vectors of *Phlebotomus* fever. The work of this commission yielded the following results:

1. *Phlebotomus papatasi* caught in a region of Palestine where the disease had not occurred recently failed to produce the disease in 8 susceptible American volunteers who were bitten by large numbers of the insects.

2. The laboratory-reared offspring of these flies transmitted the infection from one group of human volunteers inoculated with serum virus to other susceptible volunteers, although not all who were bitten developed the disease.

3. A susceptible individual may be bitten many times by many flies which have previously fed on infected human beings at the proper time and yet not develop the disease. The susceptibility to the virus was proved when the volunteer developed the typical disease following inoculation with infectious serum.

4. Carefully controlled tests with mosquitoes (*Culex pipiens* and *Aedes aegypti*) and human fleas (*Pulex irritans*) showed that they were unable to transmit the disease. Some of these data are shown in figure 2. The tests made with *Aedes aegypti* were more extensive than any of the others and were carried out both in the Middle East and in the United States with both the Middle East and Sicilian strains of the virus; the negative results are of especial interest, since this mosquito is established as a vector of dengue.

CHARACTERISTICS OF THE VECTOR, PHLEBOTOMUS PAPATASI

The term "sandfly," which is popularly used for species of the genus *Phlebotomus*, is unfortunate because in North America it is also applied to totally different minute, biting insects, which are also known as "punkies" or "no-see-ums" and belong to the genus *Culicoides*.

Phlebotomus papatasi is a yellowish, two winged, hairy midge whose body is about 2 to 3 mm. long and somewhat less than 1 mm. thick (fig. 1). Only the female of the species bites and does so during the night and early hours of the morning. The body of the female appears distended and red for some hours after a blood meal, and black for several days thereafter.

While the bite itself is usually painful, there is no reaction to it until and unless the person has developed an allergy to the secretions deposited during the bite. In persons not previously bitten by these insects there is neither pain nor local irritation after the initial stab. The bitten site may be marked by a pinpoint, reddish or hemorrhage spot or may be inconspicuous. However, about one to two weeks later (without exposure to other bites during the period) inflamed papules usually appear at practically all the sites of the original bites. These papules are 2 to 3 mm. in diameter, raised about 0.5 mm., pink or red, and not infrequently vesicular. Their appearance is not necessarily associated with itching, although moderate to severe itching is usually present later. These lesions are prominent for four

Fig. 1.—*Phlebotomus papatasi*.

to five days and then slowly disappear. Once sensitization is established such papules appear earlier after subsequent bites, and in certain hypersensitive persons there is an almost immediate urticarial reaction which may produce pronounced and extensive swelling of the eyelids or lips when these sites are bitten. Some persons, however, do not become sensitive.

These insects are most prevalent near the ground level, and only small numbers of them are encountered in upper stories. Their flight is characteristically in short, jerky hops along the walls and ceiling. They rarely bite people in motion or when there is a strong breeze. Because of their small size and capacity to penetrate small apertures, the ordinary screen and mosquito bar fail to keep them out. There is reason to believe that their range of flight is very short and that insects found in human habitations probably originate

14. Whittingham, H. E.: The Etiology of *Phlebotomus* Fever, *J. State Med.* 32: 461, 1924. Birt.¹⁰ Shortt, Poole and Stephens.¹⁰

from breeding sites within a radius of about 50 yards;¹⁵ there is some question, however, as to whether there may be exceptions to this rule. *Phlebotomus papatasi* is known to breed in rubble, dugouts, cracks in the earth, walls and embankments, garden soil and other dark protected spots containing moist organic matter. The flies are not, however, aquatic like mosquitoes, and too much moisture drowns the larvae. It has been observed that material for a possible breeding place is too damp if it adheres to the fingers and does not fall off when it is gently rubbed between them. It is apparent, therefore, that neither the sands of the desert nor the excessively moist areas of the tropics can be expected to provide suitable breeding grounds. The disturbance of ground incident to the establishment of

Phlebotomus papatasi. Secondary cases do not arise by contact in the absence of the vector. Although the disease is almost never seen among the native adolescent or adult population of endemic regions, it is obvious that practically all of them are attacked in infancy and early childhood. A good Italian description of the disease in infants and children¹⁶ (recognized as such during an epidemic among adults) indicates that the disease differs in only minor details in the younger age groups, the incidence of diarrhea being especially high among them. While it is thus clear how new susceptible subjects become available each year for the perpetuation of the virus, it is not clear what the reservoir of the virus is during the late autumn and winter months when the *Phlebotomus* flies are absent. It is

Fig. 2—Capacity of various blood sucking insects to transmit *Phlebotomus* fever.

certain military installations, such as occurs in the excavation of tent floors, the building of parapets and the erection of new buildings, can provide good potential breeding grounds. In warm weather approximately four and one-half to six weeks is required for the eggs to develop into adults. The life of the adult is believed to be relatively short in hot weather. In the laboratory it is not over two to three weeks.

CYCLE OF INFECTION AND RESERVOIR OF VIRUS

According to our present knowledge the disease is maintained in nature by passage from man to man through the medium of the intermediate host and vector.

known that the virus quickly disappears from the blood of human beings, and there is as yet no evidence that it may be carried by lower animals for either long or short periods of time. Doerr⁹ first suggested the possibility that the virus may be transmitted from one generation of infected *Phlebotomus papatasi* to another. Whittingham¹⁴ was the first to demonstrate that *Phlebotomus papatasi* reared in the laboratory in a country where the disease is unknown (England) was capable of producing the disease in human volunteers without previously feeding on infected human beings. He believed, however, that the infection was not transmitted through the ova, but rather that the larvae acquired it by ingesting the debris or dead remains of their "parents." Moshkovsky and his collaborators,¹⁷ starting with the ova from thousands of phlebotomi which had been fed on patients with the disease, proved in a series of experiments that certain of the adults raised from ova hatched away from their "parents" were capable of producing the typical disease in human volunteers. The nature of the disease they thus produced was further proved by serial passage of the virus in other human beings.

This question was investigated by this commission as follows:

(a) *Phlebotomus papatasi* larvae were allowed to ingest lyophilized virus (human serum), and the resulting adults were tested on human volunteers with negative results.

(b) *Phlebotomus papatasi* hatched out in the laboratory from ova derived from parent females of proved infectious capacity as late as eight to ten days after the infectious blood meal failed to produce the disease in human volunteers.

While these experiments were not extensive, they indicated that the virus is not passed on from generation to generation in all infected flies. Nevertheless, even if such an event should occur only occasionally, as suggested by Whittingham's¹⁴ and Moshkovsky's¹⁷ experiments, it may be enough to carry the virus over from one season to another. It is well to recognize, however, that this question cannot be regarded as having been settled.

STUDIES ON THE ACTION OF
PENICILLINI. THE RAPIDITY OF ITS THERAPEUTIC EFFECT
ON GONOCOCCIC URETHRITIS

C. PHILLIP MILLER, M.D.

WILLIAM WALLACE SCOTT, M.D.

AND

VELMA MOELLER, B.A.

CHICAGO

Although reports of the efficacy of penicillin in the treatment of gonorrhea¹ began to appear soon after the drug became available for clinical trial, not one of them has sufficiently emphasized the rapidity of its curative action. This point is brought out in the present study, which was undertaken as a part of an investigation into the mode of action of penicillin. Since infections of the male urethra lend themselves readily to bacteriologic and cytologic observations, gonococcal urethritis in the male is peculiarly suited to the study of the mode of action of a chemotherapeutic agent.

METHODS

The first 7 patients were hospitalized for treatment. Smears and cultures of urethral exudate were made on admission and before the first injection of penicillin.² Smears and cultures were made in duplicate. One of the smears was stained by Gram's method and examined at once, the other saved for later examination by special staining methods.

After the first 7 cases had demonstrated the rapidity of its action, we began to administer penicillin to ambulatory patients in the outpatient clinic, where they were kept under supervision during the period of treatment and observation. This practice proved to be equally successful in all particulars.

All patients, whether treated as inpatients or as outpatients, were examined by smear and culture at frequent intervals—every hour or two in most instances. Follow-up examinations were begun the following morning.

CULTURES

After the urethral orifice had been cleansed with 1:1,000 mercury bichloride and dried with sterile gauze, a drop of pus was accumulated by stripping the urethra and was taken up with a sterile cotton swab, small and tightly wound to prevent too much absorption. The swab was streaked at once across the middle of two agar plates which had been brought to the bedside or examining table. The inoculum on the second plate was spread out at once with the same swab, but the first plate was carried to the laboratory and spread with a sterile platinum loop. This precaution was taken in the interest of adequate separation of colonies and

minimal contamination and was justified by occasional differences between the two cultures.

The medium employed was a meat-digest agar containing phosphate buffer and 1 per cent glucose. Defibrinated rabbit's blood was added at the time the plates were poured.

The plates were incubated in an atmosphere of carbon dioxide provided by a lighted candle in one of the metal cylinders customarily used for the sterilization and storage of Petri-dishes.

After incubation overnight, colonies of gonococci were usually plainly visible, but the plates were returned to the incubator for another day and examined again. The bacteriologic diagnosis was based on morphology, staining reaction and sugar fermentation.

CLINICAL DATA

Twenty-one patients were treated in this study.³ They varied in age from 21 to 49 years, with an average age of 30.3 years. Eight of the patients had had earlier infections. As they were selected to include early untreated initial attacks and chronic stubborn infections, the duration of the present disease varied from five days to four months; in 4 cases it was three months or longer. Three of the patients had received no treatment. Their infections were 5, 7 and 8 days old, respectively. All the other patients had been treated with one or another of the sulfonamide drugs, mostly sulfathiazole. Some of the obstinate cases had received a variety of sulfonamide preparations. Additional therapy in some cases included local instillations of silver preparations or potassium permanganate and artificially induced fever. Neither the duration of the infection nor the kind and duration of previous treatment seemed to make any difference in the response to penicillin.

Complications included acute prostatitis (case 5) and 2 cases of acute prostatitis and epididymitis (one of them, case 1) and 1 case of mild acute arthritis.

METHOD OF TREATMENT

Penicillin was administered by injection of 1 or 2 cc. quantities of aqueous solution into the gluteal muscles. The water used for its solution was sterile, pyrogen free water obtained from the operating room. The total dosage varied from 50,000 to 100,000 Oxford units. The size and spacing of the individual injections varied considerably. Table 1 gives some examples of this variation.

No symptoms or signs of toxic reactions were manifested in any of the patients.

RESULTS

With one exception, every infection was brought to an abrupt termination by the intramuscular administration of penicillin. Within two or three hours after the initiation of treatment and before the course of injections was complete, the urethral exudate underwent a striking change in character and quantity. It became paler, less viscous in consistency and much reduced in quantity. By the 5th or 6th hour it had practically disappeared. Stripping the urethra produced a small drop of clear watery secretion. The following morning no discharge was apparent, and none could be produced by stripping the urethra.

Coincident with the reduction and disappearance of these signs of infection came relief from any subjective symptoms such as local tenderness and pain on urina-

2. The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for experimental investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

3. Drs. Russell D. Herrold, Frank M. Phifer and Harry C. Rolnick cooperated by referring some of these patients to the authors.

tion. In the 2 cases complicated by epididymitis, the pain and local tenderness disappeared within twenty-four hours, and the swelling subsided considerably in that time and disappeared altogether within one week.

The single exception noted was an especially severe acute hemorrhagic urethritis, which was scheduled to receive a larger course of treatment but in which by error only two doses of penicillin, a total of 60,000 units, was administered. The urethral discharge lessened in amount but never completely disappeared and increased again the next day. It responded, however, to a second course of penicillin (100,000 units) exactly like the other cases.

Cultures.—The time of disappearance of gonococci from the smears and cultures is shown in table 1, which contains illustrative examples of different doses and

morphologic changes in appearance of both the leukocytes and the gonococci.

During the second and third hours after the beginning of treatment many of the leukocytes appeared swollen and filled with large vacuoles and their nuclei denser and more deeply stained. A large proportion of the gonococci at this time were swollen, irregular in shape, not uniformly stained, and surrounded by clear zones. These changes can be seen in the photomicrographs. Their significance is being investigated.

SEPARATION OF THE LOCAL AND SYSTEMIC ACTION OF PENICILLIN

Our interest in the mode of action of penicillin led us to question whether its therapeutic effect resulted from the penicillin brought to the tissues by the blood

spacing of injections. The beginning of treatment is designated in each case as zero hour, and the times of subsequent procedures are given in terms of hours thereafter. The table also presents the results of the examination of smears and cultures made just before each injection of penicillin. The numbers of gonococci found in the smears and the number of gonococcus colonies developing in each culture are indicated by plus marks.

As shown by the results presented in table 2, the viable gonococci present in the urethra diminished rapidly and disappeared altogether in a very few hours. In fact, the interval between the onset of treatment and the first negative culture in all 15 cases averaged 3.7 hours, and the average length of time from the beginning of treatment to the first negative smear was 3.4 hours.

Cytologic Findings.—Examination of the smears which were made at the time of each culture confirmed the results of the latter and revealed some interesting

stream (systemic effect) or from the local gonococcal action of the penicillin secreted in the urine and passed over the urethral mucosa during each micturition. As the 15 patients in the first series (represented by cases 1 to 4) had been allowed to void their urine at will, it was necessary to treat two additional groups of patients differently if we were to ascertain the relative importance of the two actions of penicillin, the systemic and the local. One group consisting of 2 patients was treated solely by urethral instillations of penicillin and the second group by intramuscular injections and the retention of urine during the period of therapeutic response.

THERAPEUTIC RESULTS WITH LOCAL INSTILLATIONS ALONE

The patients were allowed to void, and 4 cc. of penicillin solution was instilled into the anterior urethra and retained for five minutes. Every two hours in 1 case and every hour in the other, smears and cultures

were made of the urethral exudate and another instillation of 4 cc. was made. One patient received 1,000 units every two hours for five injections and the other 3,000 units every hour for seven instillations.

In the first of these 2 cases the smears and cultures became negative after the first injections but were strongly positive on the following morning. In the other case neither the cultures nor the smears became negative at any time.

These 2 cases seemed sufficient to demonstrate the inability of penicillin applied locally to eradicate gonococcal infection from the anterior urethra, and no more attempts were made. Both these patients were successfully treated by intramuscular injections on the following day. The first is case 6 in table 1.

THERAPEUTIC RESULT BY SYSTEMIC ACTION ALONE

The reciprocal experiment designed to eliminate the local action of the penicillin, which washes the surface of the urethral mucosa with each urination, was carried out on 7 patients. They received intramuscular injections, as did those in the first group, but retained their urine for the period of treatment and observation. To make this possible without discomfort they had been instructed to reduce their fluid intake to a minimum the preceding day. In all cases the urethral exudate underwent the same changes in character and disappeared as rapidly as in the cases in the first series, and the smears and cultures became negative at the same rate.

The data on 3 of the 7 patients in this series are presented in table 2. In all 7 the average lengths of time from the beginning of penicillin treatment to the first negative cultures and smear were 3.8 and 3.1 hours respectively. These results are almost identical with those obtained in the first group of cases and indicate that the therapeutic action of penicillin in gonococcal urethritis is systemic rather than a local; that is, it is due to the penicillin brought to the tissues by the blood stream rather than that which passes through the urethral canal in the urine.

RESULTS OF FOLLOW-UP EXAMINATIONS

With 1 exception the patients were all followed by a systematic series of follow-up examinations, which began one week after treatment and included prostatic massage in 9 cases and provocative soundings in 2. Six patients were examined after bouts of excessive drinking. In no instance were gonococci found in cultures or smears after the examinations made during the period of treatment.

Two reinfections occurred. Both were regarded as such rather than relapses for the following reasons: One of them (case 1) occurred four months after treatment with penicillin, during which time the patient had been quite free from symptoms and had had four follow-up examinations, each including cultures, all of which were negative. He gave a definite history of exposure to account for his second infection. It was successfully treated with penicillin. Six follow-up cultures since then have all been negative.

The other occurred in case 9 a month after treatment with penicillin, during which time the patient had three follow-up examinations and cultures, all of which were negative, the last one a week before the exposure, which resulted in infection four days later. The reinfection responded promptly to penicillin.

COMMENT

Although only 21 cases were studied in this investigation, the results seem to be sufficiently striking to warrant presentation. The clinical signs and symptoms of urethritis subsided and disappeared with remarkable rapidity, in fact within two to five hours after beginning the administration of penicillin by intramuscular injection. At the same time the number of gonococci recovered by smear or culture from the urethral exudate diminished rapidly to the vanishing point. The interval between the onset of treatment and the first negative culture varied from one to six hours, with an average of $3\frac{3}{4}$ hours. The rate of disappearance was not

Microscopic appearance of smears stained by Gram's method: A, 0 hour (immediately before first injection of penicillin); B, 3d hour (after 1st injection of penicillin); C, 3d hour; D, 2d hour; E, 2d hour; F, 3d hour.

significantly slowed in those patients who retained their urine throughout the period of treatment, thereby eliminating the local action of penicillin on the urethral mucosa during urination. This finding, together with the failure of the local application of penicillin by instillation in 2 cases, indicated that penicillin is brought to the infected mucosa by the blood stream rather than from the lumen of the urethra.

The precise nature of the gonococcal action of penicillin is not understood and lies outside the field of this investigation. The peculiar morphologic changes shown by gonococci in smears at the time their numbers were diminishing most rapidly are similar to those which can be produced in vitro by the action of penicillin

cent gentian violet, as reported by Wolff, Elkinton and Rhoads.⁹ In these cases the bromsulphalein retention rose to over 15 per cent thirty minutes after injection, the van den Bergh reaction was slightly increased and the plasma prothrombin was decreased. The literature contains evidence from human autopsies that degenerative changes may occur in the liver without the use of any of the tanning agents, and Wilson, MacGregor and Stewart⁸ describe a case in which clinical jaundice occurred in which only oil was applied locally. The association of actual liver necrosis with the use of tannic acid, however, is striking in the autopsy series of Erb, Morgan and Farmer.¹⁷

The possibility remained that tannic acid would not be harmful on small burns but that with burns of more than one third of the body surface enough absorption would take place to cause fatal liver damage. The fact that patients with burns of over one third of the body surface frequently die even when no tanning agent is used and when the circulation is maintained with plasma would lead one to conclude that, although tannic acid may have been absorbed from large burns in sufficient amounts to cause some liver damage, this was seldom more than a contributory cause of death.

In summary, therefore, our present knowledge indicates that the tannic acid treatment relieves pain well, helps prevent infection in second degree burns and perhaps delays the development of infection in the deeper burns until danger from shock and toxemia have passed. It does not prevent toxemia, and if it is absorbed in sufficient quantity it is capable of producing liver damage. On the other hand, there is as yet no substantial evidence that it has increased the mortality of burns in man. It decreased the loss of plasma-like fluid from the surface of second degree burns, but there is no conclusive evidence that it has reduced the loss of plasma from the circulation into the tissues.

Numerous statistics in the literature¹⁸ indicate that its use was followed by a decrease in mortality, and we believe that it has saved many lives. Now, however, that invasive infection is so well controlled by chemotherapeutic agents it seems likely that the tannic acid method will be superseded more and more by other methods, many of which are similar to the very methods it displaced before the days of the sulfonamides.

The ultimate place of the tannic acid method will probably be based not on animal experiments nor on plastic results but on human mortality experience. Analyzing the statistics compiled by Harkins,¹⁹ one finds that without tannic acid the combined mortality for 1,369 cases was 26.7 per cent, whereas with tannic acid in a series of 1,660 cases it was 10.5 per cent. It is premature to state whether a further reduction in mortality is being made by the nontanning methods now in use.

SURGICAL CLEANLINESS, COMPRESSION AND REST

AS PRIMARY SURGICAL PRINCIPLES IN THE TREATMENT OF BURNS

SUMNER L. KOCH, M.D.

CHICAGO

In spite of the twin spurs of war and civil disaster to the study of burns we are still far from a complete understanding of the changes in the body tissues, the body fluids and electrolytes that result from a severe burn. In the past few years, however, many workers in our own and other countries have made helpful contributions to the solution of this difficult problem and have made the entire medical profession increasingly aware of its importance. McClure¹ and his able associates at the Henry Ford Hospital—Hartman, Harkins, Lam and Romence; Reid,² Siler, Altmeier and their associates at the Cincinnati General Hospital; Churchill,³ Cope, Lyons and Cannon at the Massachusetts General Hospital; Lund,⁴ Levenson and Taylor at the Boston City Hospital; Drinker⁵ and his associates at Harvard University; Dragstedt⁶ and his co-workers at the University of Chicago; Rhoads,⁷ Wolff, Elkinton and Lee in Philadelphia; Hirschfeld⁸ at the Detroit Receiving Hospital; Neal Owens⁹ at Tulane; Elman¹⁰ at the St. Louis City Hospital; Evans¹¹ and his associates at the Medical College of

From the Department of Surgery, Northwestern University Medical School, and the Children's Surgical Service, Cook County Hospital.

This paper, in a symposium on "The Treatment of Burns," is published under the auspices of the Section on Surgery, General and Abdominal.

With Dr. Siler's consent I have used almost the identical title of his excellent paper published in Surgery, Gynecology and Obstetrics in August 1942.

Virginia; Wells¹² at Hartford; Gurd¹³ and his co-workers at the Montreal General Hospital have all given time and intensive effort toward solving some of the unanswered questions in the minds of surgeons everywhere and in working out more effective methods of treating burned patients. Whipple,¹⁴ in ably directing the activities of the Subcommittee on Burns of the National Research Council, has brought together men with helpful ideas and wide experience and has helped to make their ideas and experiences available for the armed forces and medical men everywhere.

In spite of the uncertainty concerning many of the physiochemical changes in body tissues and body fluids, three simple principles have come to be recognized as of fundamental importance in treatment: the surgical cleanliness that prevents infection, the compression of the injured area that prevents fluid loss, the rest that is so important if tissues are to heal in the minimum period of time. Each of these deserves brief consideration.

SURGICAL CLEANLINESS

The relative importance of the ounce of prevention and the pound of cure is nowhere more dramatically demonstrated than in the patient with an extensive burn. With the burned surface free from infection, covered with an occlusive compression dressing and left undisturbed, a patient can remain in comfort for ten, twelve or fourteen days and "emerge from the cocoon" at the end of that period with the burned surface completely healed wherever there has not been whole thickness destruction of skin. The same injury, if infection supervenes, can result in widespread destruction of the covering tissues that have survived the initial injury, long delay in healing and all the well known sequelae of an extensive, infected open wound.

Fig. 1.—a, burned extremity covered with dressing surrounded with mechanics' waste; b, after application of elastic bandage.

We have long been aware of the rapidity with which virulent infection can develop in an unprotected open wound. Aldrich and Cruickshank,¹⁵ particularly, have

emphasized the vulnerability of burned surfaces to infection. We have been peculiarly slow in applying the simple remedy—to cover the burned surface at the very outset so as to avoid contamination; if it has been exposed to contamination, to cleanse it with care to avoid trauma and further contamination; and, finally, to "close" the open wound and keep it closed.

Fig. 2.—a, application of compression dressing over burned face; note swelling of upper lip where compression cannot be applied; b, appearance on removal of primary dressing seven days after admission.

To cover the burned surface at the earliest possible moment is simply to recognize the oft demonstrated fact that the most important sources of wound contamination are the uncovered mouths and noses of the patient and of every one about him. To cover the wound immediately with the cleanest protective at hand and eliminate those potential sources of infection is simple common sense.

If the open wound has been contaminated before the patient comes to us it is equally logical to attempt to convert it into a clean wound by simple soap and water cleansing, carried out with care to avoid trauma and to avoid further contamination. Concerning the necessity and wisdom of this procedure there has been considerable difference of opinion, owing in large part to the successful results obtained in spite of its omission at the Massachusetts General Hospital after the Coconut Grove disaster. There the burned surfaces of the patients were simply covered in the emergency room with sterile towels and shortly afterward with non-adherent gauze and occlusive pressure dressings. One may point out, however, that these cases were not typical of the cases of severe burns that come to the hospital day after day. They had had no first aid care; they had undergone a minimum of exposure to external contamination; they reached the hospital within a very brief period after the disaster occurred. Under these circumstances, and in view of the large number of cases demanding attention, no one, I think, would question the wisdom of the method of treatment carried out at that time.

What happens much more often, certainly with patients admitted to the Cook County Hospital, is that the patient has received extensive, often ill advised, first aid treatment—application of greasy ointment, butter, lard—whatever the corner drug store or home can furnish, and several hours after this application, carried out under voluble mouths and weeping eyes and noses, the patient is admitted to the receiving ward of the hospital.

12. Wells, D. B.; Humphrey, H. D., and Coll, J. J.: The Relation of Tannic Acid to the Liver Necrosis Occurring in Burns, *New England J. Med.* 226: 629-635 (April 16) 1942.
13. Gurd, F. B.; Ackman, D.; Gerrie, J. W., and Pritchard, J. E.: A Practical Concept for the Treatment of Major and Minor Burns, *Ann. Surg.* 116: 641-657 (Nov.) 1942.

After such first aid treatment given three, six, twenty-four hours before the patient is admitted to the hospital, to attempt to convert the injured surface into a clean wound again seems to me simply common sense. Needless to say, one would insist on gentleness, the use only of soft cotton and plain white soap (never scrub

cleansing can be of definite aid is indicated by cultures obtained before and afterward. One might say with some justification that swab cultures made after cleansing of a burned surface do not adequately represent the conditions present; but if the original culture shows a great variety of organisms present before cleansing is

Fig 3—Appearance immediately after removal of compression dressing eight days and seven days after injury, note in patient at right absence of swelling in soft tissue of lids

Fig 4—a, appearance of patient on admission one hour after injury, b, compression dressing, c, appearance on discharge, eight weeks after injury

brushes or tincture of green soap), irrigation with warm salt solution and the surgical cleanliness routinely employed in a well regulated operating room—masks, sterile gloves, thoughtful care to prevent additional contamination. Loose destroyed tissue which has not been washed away I should always lift away with sterile forceps and scissors. Blisters can be left untouched. Most of them will probably give way under a well applied compression dressing. That such

begun, and if many of these fail to appear subsequently during the process of wound healing, such findings seem to me significant.

One would admit freely that there are borderline cases in which good judgment must be exercised as to what should be done and what omitted; and it is unnecessary to add that often treatment to anticipate or relieve shock must go hand in hand with local treatment

THE DRESSING

To cover the burned surface with a nonadherent dressing which permits drainage through it and which can be removed with a minimum of difficulty when removal is indicated seems an entirely logical thing to do. Whether the fine meshed gauze applied directly to the wound surface should be impregnated with petrolatum, boric acid ointment, xeroform ointment, ointment containing zinc peroxide, sulfathiazole, sulfanilamide or sulfadiazine or simply saturated with salt solution is one of the details concerning which there is not sufficient evidence available to permit one to make dogmatic statements. My own preference has been for simple petrolatum, though more recent experiences support the observations made by Meleney^{15a} and others that the use of polyethylene glycols containing 20 per cent zinc peroxide is more helpful in controlling potential infection. The fact that a simple nonirritating dressing provides favorable conditions for wound healing is well demonstrated by Cope and Cannon's¹⁶ study of the rate of healing under various methods of treatment of donor sites after removal of skin grafts, and by Hirshfeld, Pilling and Mann's⁸ study of the comparative effect of tanning agents and petrolatum gauze on fresh wounds.

To cover the nonadherent gauze with sufficient gauze and mechanics' waste to make possible compression of the entire injured surface is the application of a simple method of arresting fluid loss. When confronted with bleeding, one's first impulse, whether layman or surgeon, is to apply direct pressure and stop the bleeding. Curiously, if we cannot actually see the bleeding we do strangely illogical things: apply ice bags, inject procaine hydrochloride (for the bleeding that follows a sprain), perhaps make incisions to relieve tension. Not often enough do we apply the simple principle of applying direct pressure when the site of bleeding is under the surface and when it involves a considerable area.

The fact is inescapable that the exudation of plasma that occurs from a burned surface and into the soft tissues underneath it is exactly comparable to the hemorrhage that occurs into the soft tissues following a crushing injury. It can be checked and limited in the same way—by the application of a compression dressing over the injured area.

It is scarcely necessary to point out that such a dressing should be a compression dressing and that it should not cause constriction or restriction of the circulation. If an extremity is involved, the dressing should begin at the tips of the digits, and the individual digits should be separated. Once properly applied, it should be supported with splints and left alone. If an extremity is involved, elevation of the part brings the aid of gravity to the return circulation and helps to prevent stasis and discomfort.

REST

Hugh Owen Thomas's dictum "Inflamed and injured tissues need rest" could well be emblazoned over the

doorway of every surgical ward. Many of us can recall the days of our internship when it was considered proper and necessary to dress the burned areas of the injured patient each day from the time of his admission to the hospital. I look back with dismay to the injury I inflicted in years gone by on burned patients by repeatedly tearing down the tissue nature was trying to rebuild and by constantly exposing large open wounds to reinfection from the dust of the ward, from my own hands and from my uncovered mouth and nose. Yet I was trying to carry out the teaching and follow the practice of my attending surgeons.

Every surgeon and every burned patient is under everlasting debt to Davidson¹⁷ because he taught us to "close the open wound"; and, since the coagulant

Fig. 5.—a, appearance of patient on admission two hours after injury; b, after cleansing; c, compression dressing; d, on discharge, nineteen days after injury.

crust that he devised could not be easily removed, we learned the wisdom of keeping the wound closed, of not subjecting it to repeated injury and of keeping it at rest.

That a tannic acid crust is not the most satisfactory means of attaining these objectives and that it has some serious disadvantages does not nullify Davidson's work, or the great impetus he gave to efforts to provide better care for burned patients.

Since 1925, when Davidson first advocated closing open wounds with a tannic acid crust, we have learned that the same closure can be obtained by a simple nonadherent dressing which does not produce coagulation of undamaged cells remaining over the burned area and which can and should be left alone, if no

infection is present underneath it, until reformation of destroyed epithelium is as complete as possible. It has been demonstrated time and again that, if the whole thickness of the skin has not been destroyed, complete healing of the burned surface takes place in from ten to fifteen days if only infection can be prevented, if the injured surface is protected by the compression dressing and if the all important "rest for injured tissues" is maintained. The same conditions favor separation of the destroyed tissue if whole thickness destruction has taken place and help make possible early replacement by transplantation of skin from another part.

SUMMARY

The logical treatment of burns is based on three simple premises: 1. A burn, as Mason¹⁸ pointed out so clearly, is essentially an open wound involving the

Fig 6—Appearance of burned surface twenty days after admission. With aid of indwelling catheter and good nursing care burns about the perineum can be kept covered with compression dressings throughout the period necessary for wound healing.

superficial tissues and is subject to the same serious complications—infection and hemorrhage. 2. Both infection and hemorrhage can be prevented by well directed treatment at the very outset. The essential features of such treatment are surgical cleanliness, compression of the injured surface to prevent fluid loss, and rest. If infection and hemorrhage are not prevented, control of either or both can become exceedingly difficult. 3. If the injury has resulted in complete loss of covering tissues, replacement at the earliest possible moment is most certain to result in prompt healing, with maximum retention of function.

54 East Erie Street.

THE EARLY PLASTIC CARE OF DEEP BURNS

FRASER B. GURD, M.D., C.M.

AND

JOHN W. GERRIE, M.D., C.M.

MONTREAL

Prior to 1925 in the treatment of burns, despite the fact that in all major clinics a high mortality was encountered, comparatively little attention had been paid to the victim of such a disaster. In that year the late E. C. Davidson commenced the publication of a series of articles which in recommending the tannic acid treatment of burns drew attention to the fact that loss of plasma was one of the major causes of death. Davidson's contributions were followed by an enormous increase in the interest shown in the treatment of the burned individual. During the ensuing years gradually more and more attention has been paid to the problem and, with the commencement of hostilities in September 1939, the problem of burn therapy has become one of the major interests of all surgical services in the armed forces.

One of the important features of this increased attention to these problems has been a recognition of the fact that skin is the most useful covering for a burned surface; that not only is plasma loss minimized and progressive hypoproteinemia halted by early skin coverage but that late deformity and disfigurement are thus minimized, and, more particularly perhaps, that the morale of the victim is improved. In our clinic at the Montreal General Hospital it has been one of our chief aims to plan the treatment of the burn wound so that early covering by means of skin grafting might be carried out.

A burn due to heat may be considered as a wound which is accompanied by special features, notably an immediate threat to life, owing to the particular form of shock which characterizes the lesion and the later threat due to toxemia, sepsis and nitrogen imbalance and, secondly, a widespread loss of surface tissue as compared with the depth of it.

Although tannic acid and other escharotics appear to have had a favorable effect in lowering immediate burn mortality, such methods delay the employment of skin coverage by grafting. This delay is due to several facts, namely (1) that the tanned tissue is frequently difficult to remove at an early date, (2) that suppuration beneath the tan has proved a bad feature in many cases and (3) that, as a result of the foregoing, exhaustion of the patient occurs so that, on the one hand, operative intervention must be delayed and, on the other hand, failure of grafts to take is probable. Gradually, and except under very special circumstances, the employment of tanning methods has been discarded in our Montreal General Hospital Clinic during the past three years. Effective shock and toxemia treatment with newer methods of controlling nitrogen imbalance and logical wound dressing care have resulted in a decrease in the mortality rate, and early and timed skin grafting has lowered morbidity and deformity.

Skin grafting is best started as soon after control of the shock and toxemia phases as the patient's con-

dition will permit. Theoretically this is before the burned areas pass into a phase of chronic infected granulations and the patient into a state of inanition and chronic protein loss. We are convinced that it is unwise to postpone grafting while waiting for problematic epithelium to grow in from the edges of the wound and for doubtful hair follicle and sweat gland epithelium to reach the surface and spread. The patient with an extensive burn recovers in proportion to the speed and extent of skin coverage. There is an optimum time, and we believe this to be early, when it is advisable to step in and surface the denuded area. In a recent publication from our clinic we¹ have stressed the importance of timing in burn treatment. By timing we have meant that a plan should be laid down so that each step in the treatment of the burned patient should be clearly indicated in a routine sequence. Part of this routine has been that a surgeon trained in plastic surgery is added to the shock and burn teams from the very outset. The plastic surgeon is made, therefore, a member of the team on which the time procedure is based from the first. He is available for advice and also to carry out whatever operative intervention for skin coverage is deemed advisable.

ASSESSING THE BURN DAMAGE

At the outset the significant features of the burn history and the clinical appearance of the burned areas are carefully assessed and are of considerable value in

Fig 1 (case 1)—Appearance on sixteenth day at first redressing, with the deep burns on the right side of the abdomen and thigh obvious, superficial burns healed.

“timing” the course of the future treatment. This assessment is the most reliable guide to burn depth and the probability of skin grafting to come. A scald from moderately hot liquid with an erythematous or lightly blistered skin will undoubtedly be a superficial burn, healed at the first redressing. A pressure steam burn or burn from excessively hot liquid with wide blisters and intervening searing will be deeper (figs. 1 and 2) and the plastic surgeon is “timed” in, is present at the first redressing and is prepared to go ahead with skin surfacing as indicated. Flash burns are of the same type. Flame burns as from ignited clothing are more uniformly deep (figs. 4 and 5), the skin is seared, and skin grafting will be required. Electrical burns are bad and there is often deep loss of tissue with coagulation which may further complicate the skin grafting which may follow. The plastic surgeon or one ready to carry on this work stands by at each redressing at ten to fourteen day intervals, prepared to carry out the necessary skin surfacing as early as feasible.

1 Gurd, F. B.; Ackman, D.; Gerrie, J. W., and Pritchard, J. E.: A Practical Concept for the Treatment of Major and Minor Burns, *Ann Surg* 116: 641-657 (Nov.) 1942.

In assessing the burn damage, the extent is calculated and recorded according to Berkow's tables. In estimating depth we have discarded all previous classifications, since they tend to confuse. The only useful classification, we believe, is that which indicates the eventual therapy required. Thus we have the super-

Fig 2 (case 1)—Appearance at redressing ten days later with donor site on the left side of the abdomen healed and complete take of the grafts on the right.

ficial burn in which the epithelium will show quick regeneration or the deep burn which will require skin grafting.

The use of sodium fluorescein as described by Dingwall² may prove to be a help in assessing this matter of depth. How to incorporate the test in the “timed” treatment of burns is the problem.

THE OCCLUSIVE PRESSURE DRESSING OF THE BURN WOUND

The important principles of dressing in preparation of the burn wound for skin grafting are (1) rest, (2) infrequency, (3) occlusion and (4) pressure. To this is added a sulfonamide effect from a 5 per cent oil in

Fig 3 (case 4)—An extensive body burn at the first redressing on the tenth day. This patient was completely grafted at the third redressing, on the thirtieth day, with isodermal grafts from the mother and auto-dermal grafts from the patient's back.

water emulsion of sulfathiazole prepared according to the Montreal General Hospital formula, as outlined by Ackman and Wilson.³ Pressure keeps down edema,

3. Ackman, D., and Wilson, G. Surgical and Gynecological Experiences with an Emulsion of Sulfathiazole, *Canad M. A. J.* 46: 209-214 (March) 1942.

prevents fluid loss, promotes healing, prevents exuberant granulation and effectively replaces the eschar treatments. Infrequency of dressing and occlusion prevent cross infection and bathe the wound in an exudate which contains whatever immune bodies may be present. In none of our cases has a streptococcal infection complicated the picture. In the 5 per cent sulfathiazole oil in water emulsion we have an effective local agent, we believe superior to boric acid or petrolatum dressings. The sulfathiazole is active in the water phase of the emulsion, does not cake, has been found present in the granulations up to 120 mg. per hundred cubic centimeters and has never given us a blood level of over 3.5 mg. per hundred cubic centimeters and rarely over 1.5. It is our opinion that the presence of sulfathiazole in the recipient graft bed up to these percentages in no way hinders but rather enhances graft take.

This dressing is placed following gentle soap and water washing and minimal débridement, with use of operating room technic, as soon as the patient's condition and the exhibition of shock therapy permit. The burned wound is shingled with 4 by 6 inch cuts of wide mesh lace (Nottingham lace of a bastard weave with 11 strands to the inch) well buttered with sulfathiazole emulsion (fig. 4). A liberal layer of emulsion is placed over the wide mesh lace and the dressing completed with surgical gauze, cotton waste to a depth of 4 to 6 inches and flannel bandage cut on the bias and reinforced with adhesive tape (fig. 5). The wide mesh lace tends to splint the wound surface and to provide a base for the dressing, which shows little tendency to slip. At no time have granulations become enmeshed in this or been a bothersome feature. On leg or arm burns, thin plasters may be added to prevent ankle, wrist or shoulder movement. This dressing (fig. 5) is infrequent. The patient is comfortable and, if the general condition permits, can be transported without fear of damage or contamination. This dressing is not removed, and there is no reason to remove it until the tenth to the fourteenth day. It is then taken down in the operating room and either (1) the burn wound is healed or early complete repair is evident or (2) it is grafted in whole or in part and redressed by the same technic for another ten to fourteen days or (3) grafting is deferred and the wound redressed

Fig. 4 (case 4).—The wide mesh sulfathiazole lace being applied.

by the same technic for another ten to fourteen days. In this way the whole burn treatment is "timed" into a series of one to five or six dressings at ten to fourteen day intervals with no intermediate dressings.

TIMING OF THE SKIN GRAFTING

In the treatment of wounds, whether operative or due to trauma, closure may be accomplished by either primary suture, delayed primary suture or secondary suture. For many years McKim and one of us (F. B. G.) have believed that in the care of wounds

due to trauma the advantages of delayed primary and secondary suture have not been fully appreciated. In this communication we suggest that as far as the skin coverage of burns is concerned a similar terminology may be used and that there is a place in burn therapy for primary skin grafting, delayed primary skin grafting and secondary skin grafting.

Fig. 5 (case 4).—The complete dressing with a surgical window over the umbilicus for wound bacterial cultures.

1. Primary skin grafting is analogous to primary wound suture. Under the name of immediate grafting it has been described by Forrest Young⁴ and was suggested by Sir Harold Gillies on his recent trip to this country when he showed a four day old burn so treated. It is theoretically sound, as the burn is excised, the wound grafted and the area healed by first intention in a week or ten days, a minimum deep burn morbidity. However, it has a very limited applicability and is indicated only in obviously deep, circumscribed burns where there is no evidence, or likelihood, of shock. Few burns come into this category.

2. Delayed primary grafting of burns is analogous to delayed primary suture of wounds. The grafting has been delayed while the general condition of the patient and the local condition of the wound have been made ready. This is the usual and desirable type, and the aim of our clinic has been to graft most burns between the first and third dressings, the tenth to the forty-second day. The burn wound is dressed in an occlusive pressure sulfathiazole dressing and the decision to graft delayed until the tenth to the fourteenth day, when the shock and toxemia phases are passed and the first redressing is done. From the standpoint of the average patient's general condition, this is the optimum time for skin grafting, as it is before the period of inanition and chronic protein loss sets in. The local condition may not be ready but can often be prepared by judicious surgical excision of slough. The local condition is ready for grafting when slough and depth become apparent and before granulations become too obvious. It is at this stage that a test with sodium fluorescein might be helpful. The local area should be ready for a delayed primary graft at the first, second or third ten to fourteen day dressing.

3. Secondary skin grafting from six weeks on is undesirable but may be necessary in cases of badly infected wounds in emaciated patients in whom the burn wound was not initially controlled. It may be necessary in cases treated at home or in isolated areas where skin grafting was not available or its advantages were not realized.

4. Young, F.: Immediate Skin Grafting in the Treatment of Burns, *Ann. Surg.* 116: 445-461 (Sept.) 1942.

ISODERMAL GRAFTING

Autodermal grafting, or the use of the patient's own skin, is preferable. Isodermal grafting, or the use of skin from other than the burned individual, is in the nature of a temporary dressing. It has a limited applicability, as in the case of a child recently seen with extensive burns whose own skin proved inadequate and whose general condition was bad.

Isografts dissolve and disappear in three to six weeks. The literature to date has not been very hopeful of securing permanent isodermal grafts of any sort. Padgett⁵ tried isografting in 50 well controlled cases and concluded that isodermal grafting was not practicable. Bettman⁶ advocates it as a life saving measure. Brown⁷ reported 1 case of successful homografting, a small experimental graft from 1 identical twin to the other. However, the whole question of temporary isodermal grafts in the nature of a burn dressing is still wide open. Time⁸ has set its stamp of approval on the method, giving publicity to the voluntary donation of convict's skin to burn sufferers and the establishment of skin banks. A recent article by Sachs and Goldberg⁹ on foreskin isografts is reassuring and worthy of further work and substantiation. They stress the point of using skin from the newborn and premature infant in that its growth potentialities are greater. They believe that 65 to 75 per cent of their transplanted skin has survived and have been able to identify some grafts eight months later. This may open the possibility of refrigerated skin banks for burn emergencies.

INFLUENCE OF INFECTION ON GRAFTING

In none of the cases that have been under our control from the time of injury has infection delayed grafting. In a number of cases prior to admission to the hospital moderately severe infection with accompanying inflammatory reaction had already become established. In all of the latter group of cases the ulcers were ready for grafting after the application of but one dressing, that is at the end of from ten to fourteen days. The occlusive pressure sulfathiazole oil in water emulsion dressing in our experience has controlled or so moderated infection that grafting may be successfully carried out. At no time after the first redressing have we been able to culture streptococci, *Bacillus pyogenes* or *Proteus vulgaris*, the micro-organisms which seem to have the most deleterious effect on skin grafting. Although we have usually been able to culture *Staphylococcus aureus*, these have been present in but small numbers, and have not proved to be of importance. To summarize our experience in this regard, therefore, we feel justified in making the statement that controlled staphylococcus effects are not a contraindication to skin grafting when the technic recommended in this contribution is employed. The more serious infections have not in our experience occurred.

GRANULATIONS AND GRAFTING

Exuberant granulation tissue is an abortive attempt at wound healing that has been unsatisfied by epithelial covering at the appropriate time. It decreases the certainty of graft take and increases subgraft scar. Skin grafting of burned surfaces is therefore preferable

before granulations become obvious. Exuberant granulations are the result of prolonged wound treatment and are no serious contraindication to skin grafting provided they are removed. It is preferable to remove exuberant granulations and graft rather than to give them prolonged treatment to render them less exuberant before grafting. The removal is done by a scraping motion with sharp scalpel rather than a slicing procedure. This provides a more even base with less bleeding. They are taken down to the firm yellow base from which they spring. The scalpel is preferable to a curet. Bleeding is, as a rule, easily controlled by the application of hot packs and the prompt application of the skin graft, which itself seems to have a pronounced hemostatic effect. Sutures or ties are seldom necessary to control hemorrhage.

THE CHOICE OF DONOR SITES

The choice of a donor area is occasionally influenced by the site and extent of the burn and the sex of the patient. With small burns in female patients it is well to take skin from the buttocks, loin or abdomen, or some place in keeping with the trend of increasing exposure in women's styles. In a limited arm or limb burn it is convenient to take skin from an adjacent area. In extensive burn cases one finds the skin where one may and hopes there will be enough. In such severe burns it is well to take extremely thin grafts and plan on cutting successive crops from the same donor sites.

Various body surfaces present definite anatomic features making them suitable, or otherwise, for skin donation. The Padgett dermatome makes all body surfaces available, and reasonably large and even sheets of skin may even be cut from the back or front of the chest cage.

Histologically, back, loin and buttock skin are most suitable and large sheets may be taken to considerable depth. These areas provide both a thick epidermis and dermis with excellent healing qualities. Abdominal and bicipital skins are thin, especially in young patients. Inner thigh skin is also thin, the outer thigh being of an intermediary type. The abdomen and front chest areas present dressing difficulties and tend to move with respiration even under our occlusive pressure dressings, with a resultant delay in healing.

The back, loin and outer thigh have been our donor sites of choice. They are dressed in identically the same way as the original burn with an occlusive pressure sulfathiazole dressing that is not removed for two weeks. The site is then usually healed or nearly so, is brought out into the air as quickly as possible and is massaged with petrolatum or olive oil. Prolonged dressing of donor sites tends toward maceration and further skin destruction or delay in healing.

THE TECHNIC OF FREE SKIN GRAFTING

The Padgett dermatome has taken some of the "ifs" out of skin grafting and has many advantages over the older knife and razor methods. It is not fool proof, and one must become familiar with the vagaries of knife, cement and drum. If used with care and understanding, even sheets of skin may be cut from almost any part of the body. It has the advantage of calibrated adjustment, and even thickness may be cut from 0.006 of an inch to full thickness of the skin. The Blair-Brown knife and suction box technic¹⁰ has been an excellent method, especially in the hands of experts.

but the consensus seems to be that the dermatome has even more to offer. The Marcks attachment to the Blair-Brown knife is possibly a further refinement of this method.

Thick grafts are less certain of take than are thin grafts, but the thick graft contains more of the elastic tissue of the dermis and is therefore of a better texture. In the early burn wound it is well to concentrate on take rather than on texture. The latter can be corrected later, if necessary. It is the opinion of our pathologist, Dr. J. E. Pritchard, that some of our thin grafts have acquired additional subgraft dermis and its contained elastic tissue in the course of time. Our preference has been for grafts between 0.008 and 0.016 inch in thickness, which is on the average 50 per cent, or less, of the total skin depth.

The dermatome is set up on a separate table and, if possible, the wound preparation and skin grafting are kept as separate procedures. The skin is sliced off to the desired amounts and depths. The thinner grafts are usually transferred to sheets of our wide mesh lace buttered with sulfathiazole emulsion. The skin adheres to the lace, so that it is more easily handled, since the surfaces which are at least partially covered by cement are prevented from sticking together. The lace and skin are sewn in; the lace helps to "fix" or "snub" the skin into position. If thicker skin is used, it is sewn in alone without the intervention of the lace, as it contains too much elastic tissue and curls away from, and will not adhere to, the lace.

The amount of skin transferable at one operation is limited only by the amount of time available and the patient's condition. In extensive burns it is wise to have two teams at work, one cutting the skin and the other sewing it in place. In this way maximum areas of skin may be transferred at one operation. Grafted and ungrafted areas are dressed together as was the original burn and left for ten to fourteen days before another intervention. If, at this next dressing, skin coverage is complete or nearly so, sutures are removed and the graft and donor sites exposed to the air and given petrolatum or olive oil massage.

SKIN GRAFTING THE BURNED FACE

Burns of the face present a different problem to those of other parts of the body. Free skin grafting, at best, is not a satisfactory method, since it is so likely to result in a "patchwork quilt" appearance. Skin transferred from other parts of the body usually tends to retain its own color and texture or, what is worse, to become pigmented in an unsightly fashion. It is clear that the surface of the eyelids must be replaced early, since serious injury to the eyeball may otherwise be suffered in consequence of the ectropion which is sure to develop. Similarly, repair of ectropion of the lips, particularly of the lower lip, should be an early procedure chiefly because the drooping which occurs under these conditions has such an unfavorable effect on the patient's morale. The grafting of skin to other parts of the face should however, we believe, be postponed for many weeks in most cases since, in addition to the unpleasant appearance of the grafted face, it is clear that on the one hand deep burns of the face are comparatively unusual, and on the other hand the skin of the face exhibits an unusual capacity for epithelial regeneration from deeply placed hair follicles and sweat-glands.

It is a matter of common knowledge that the cartilages of the ears and nose are very liable to necrosis

as the result of burns and that large portions are often lost. The repair of these and other gross deformities becomes the problem of late reconstruction and is not discussed in this contribution.

It should be an axiom that "face skin is best for face reconstruction." As a general principle we believe that a scarred face is preferable to the masklike effect which follows free grafting in the early post-traumatic period.

BURNED PATIENTS GRAFTED

A survey of the last 100 consecutive skin grafting operations that we have performed shows that there were 35 delayed primary grafts in 22 burn patients. In addition, 12 skin grafting operations were carried out on 8 patients for the late reconstruction of burn deformities. This is a total of 47 out of 100, or 47 per cent of our skin grafting operations for primary or secondary reconstruction of the burned patient. It is thus seen that approximately one half of our skin grafting procedures have been rendered necessary on account of burns.

REPORT OF CASES

A few instructive cases are briefed, with comment on the lessons learned:

CASE 1.—A 35 per cent scald in a 14 month old girl admitted in severe shock. Wide blisters with intervening "white leather" areas. Shock treatment and an occlusive pressure sulfathiazole emulsion dressing within four hours of the accident. Excellent recovery from shock. First redressing on the sixteenth day, when the superficial burns were found healed and the deep areas obvious (fig. 1). The sloughs were surgically removed and covered with skin of 0.008 inch thickness from the opposite side of the child's abdomen. Second redressing ten days (fig. 2) later with complete graft take, and child discharged three days later.

This case, in our opinion, exemplifies ideal "timed" treatment of a severely burned patient with a minimum period of morbidity. Early skin coverage, moreover, anticipated and so prevented the onset of exhaustion due to nitrogen imbalance.

CASE 2.—Circumscribed, obviously deep burn of the thigh 8 by 6 inches in a man when a motor car engine was pushed against the thigh in an accident. Treated as an outpatient and sent in for grafting on the thirty-fifth day. Placed in occlusive sulfathiazole dressing and grafted four days later with complete take. Discharged fourteen days after grafting with complete healing.

This would have been an excellent case for immediate primary grafting. The patient might then have been in the hospital only fourteen days from the time of burning until complete healing. There was a lapse of thirty-five days in "timing."

CASE 3.—A 55 per cent extensive deep burn of the abdomen, thighs and legs of a man from burning clothing. Remarkable recovery from shock and toxemia. In excellent physical condition from the fifteenth to the thirtieth day, with subsequent progressive decline from inanition and hypoproteinemia. Because of extensive slough, grafting was deferred until the fifty-fifth day. Further grafting on the sixty-ninth day, with death three days later from chronic protein loss.

We believe that this patient might have lived if operative removal of burn slough and the application of grafts had been instituted about the fifteenth day and carried on progressively while the patient was still in good condition. Such a case also would now receive the high protein instillation into the digestive tract, as recommended by Charles Lund and his associates at the Boston City Hospital.

CASE 4.—A 30 per cent deep flame burn of the abdomen, thigh and lower leg of a 23 month old boy. Occlusive sulfathiazole pressure dressing routine from the start, but grafting delayed until the third redressing (fig. 3) on the thirtieth day because of the extent of the burn and the depth of the slough. The thigh and lower leg were completely covered with 0.008 inch skin from the mother's buttock and the abdomen with 0.008 inch skin from the child's back, in one operation. Definite improvement in the child's condition. At the fourth dressing, on the fortieth day, the child's skin had taken completely on his abdomen and the mother's skin about 80 per cent on the thigh and leg. This will be redressed at ten day intervals and the thigh and leg regrafted with the child's own skin, if and when the mother's skin disappears.

An example of extensive skin coverage at one operation using autodermal and isodermal grafts. This is a recent case; we are consequently unable to report a final result.

CONCLUSIONS

1. Skin grafting of the burned area at the earliest possible moment is one of the chief aims in burn treatment. Such a procedure minimizes protein loss, prevents contractures and maintains morale.

2. An occlusive pressure dressing with a 5 per cent sulfathiazole oil in water emulsion, timed at infrequent intervals, has been helpful in achieving this result.

3. Delayed primary skin grafting between the tenth and fortieth days is the usual technic. Occasionally immediate primary skin grafting may be indicated.

4. Isodermal grafting has a limited but perhaps valuable applicability.

5. Under the occlusive pressure dressing routine infections are seldom bothersome and do not delay grafting.

1538 Sherbrooke Street West.

THE LATE PLASTIC CARE OF BURN SCARS AND DEFORMITIES

JOHN STAIGE DAVIS, M.D.

BALTIMORE

The enormous increase in the number of burns of all types, caused by all sorts of agents, which are the direct result of waging war on land, on the sea and in the air will necessarily increase the number of burn scars, many of which will eventually have to be treated by plastic repair.

The status of the modern methods of burn treatment in all its phases has been considered in the preceding papers of this symposium. In completing the symposium the late plastic care of burn scars and deformities is dealt with, and in preparing this contribution I have drawn freely from articles which I have previously published on the treatment of scars of various types.

The earliest paper of importance which appeared in the United States on burn scar contractures and the innumerable subsequent deformities was written by Thomas D. Mütter, professor of surgery in Jefferson Medical College, Philadelphia, and was published more than a hundred years ago, in July 1842, in the *American Journal of the Medical Sciences*. His remarks on burn scars and the methods of handling them by operative procedures are well worth while reading today by any one interested in the subject, and some of his procedures are good practice still.

This paper, in a symposium on "The Treatment of Burns," is published under the auspices of the Section on Surgery, General and Abdominal.

With the newer methods of treating burns, which are designed to eliminate infection and prevent the loss of serum and in which early skin grafting or flap shifting is done to induce healing, the occurrence of objectionable scars and of subsequent deformities due to scar contractures should be much less common than heretofore has been the case. However, in spite of these new methods burn scars still occur, and contractures may still form in those instances in which the full thickness of the skin and various depths of the underlying tissues have been destroyed.

The vast majority of burn contractures, and the deformities caused by them, must be treated by operative methods, and there is little that is new in the procedures which have been found most effective in dealing with them.

Burn scars and burn contractures are probably more consistently botched than any other group of cases, and this is largely because they are deemed simple and are attempted by nearly every surgeon in whose hands they may happen to fall or to whose service they may be admitted. The care of these contractures should be only in the hands of surgeons skilled in plastic repair, who have a thorough knowledge of how to deal with scar or scar infiltrated tissue and who understand the possibilities of its utilization.

It is a sound plastic principle that when scar tissue is present it should be completely removed before attempting repair by suture, by skin grafting, by flap shifting or by flap rotation. In many instances, however, it is obviously impossible on account of the size of the scar and the situation to excise it completely and carry out any of the procedures just mentioned. In these cases scar tissue can and should be utilized in accomplishing the final restoration.

The surgeon who is inexperienced in the handling of scars will frequently operate early on burn scars of all types, apparently not realizing that nature assisted by massage and physical therapy, and sometimes by carefully given x-ray or radium therapy, will in the course of months materially change the character and appearance of the scar. My own practice is to wait until at least six months have elapsed after healing is complete before operating; in other words, until the scar is matured. In this way useless operations are avoided and procedures which would have been required had the operation been done early are frequently found unnecessary. Furthermore, if it is advisable to utilize scar or scar infiltrated tissue in the final repair, the circulation is better, the scar is softer and suitable areas may be shifted as flaps with considerable advantage. It has been my observation that the employment of scar tissue in the final repair is not utilized nearly as often as it can and should be.

All types of scars may follow burns, and the character of the scar depends on the depth of destruction, on the extent of the burn and the location, and on the rapidity and character of the healing. Scars may be unstable, smooth (skin level), depressed, adherent contracted and keloidal in type. More than one type of scar may be present on the same patient following the healing of the original burn. Any one or all of these may cause deformity and loss of function. Pain may also be a symptom in any type of burn scar. The deformities caused by burn scars range from very slight skin defects and contractures to the most horrible distortions of all parts of the body.

The power of scar contractures is very great and may cause a variety of unusual deformities, for exam-

ple drawing the shoulders toward each other, or completely dislocating joints.

In burn contractures of the neck, chest and chin the shape of the mandible is often distorted, and the full development of the bone is checked by scar pressure. The alveolar process is frequently turned outward and the teeth forward and even downward in severe cases. Long bones may be bowed, and joint surfaces may be angled. In certain old extensive burn scars with adhesions, for instance between leg and thigh or thigh and pelvis or the arm and chest, it is advisable to do the relaxing operation in stages, as shortening of muscles under contracted scars and also shortening of vessels and nerves must be thought of. The friability of bones due to the atrophy of disuse is also of importance.

The location and extent of the scar modify prognosis and treatment. In the late plastic care of burn scars and deformities a number of methods may have to be employed, either singly or in combination, as there is no one procedure of choice which is applicable for the relief of all types of cases.

The most important procedures are excision with closure by sutures; excision with skin grafting; excision with lateral relaxation incisions in adjacent normal tissue, advancement to cover the original defect, with skin grafting of the relaxation defects; gradual partial excision with closure; the use of relaxation incisions in the scar itself with skin grafting; the use of Z-plastics; the use of skin grafts of various types, and the use of pedicled flaps. All of these maneuvers must be understood by the surgeon doing this work, and his judgment should be good enough to select the method, or combination of methods, which promises the best results in each individual case. These methods will be considered briefly, and then the various types of scars and the procedures which in my experience are most suitable for their correction in various regions will be taken up.

In my own operative work on burn scars I have found it advantageous to mark out with 5 per cent brilliant green in 95 per cent alcohol all the incisions to be made. This is most helpful in planning relaxation incisions and procedures such as Z-plastics, in tissue made up of scar or strongly infiltrated with scar. When scar is incised, it is quite remarkable in certain instances to note the retraction of the wound edges and, where scar flaps have been released, to note the extraordinary changes in line of pull into unexpected directions.

OPERATIVE METHODS OF TREATING BURN SCARS AND DEFORMITIES

Excision.—When it is possible, a burn scar which lends itself to such treatment should be excised completely and the wound closed in layers. If, after excision, closure is not possible, even with undercutting, then the defect may be skin grafted with the selected type of graft.

Another method which is very helpful, the principle of which was well known in the time of Celsus, is that, when the scar has been excised and the wound cannot be closed by suture, to make relaxation incisions in the normal tissue beyond the defect on one side or both down to the deep fascia if necessary and then undercut the tissue, making a double pedicled flap. This flap may then be immediately advanced to cover the defect left by excising the scar or, if circulation is doubtful, may be sutured back into its original bed to be used later as a delayed transfer double pedicled

flap. The method may be modified by forming the double pedicle, delayed flaps, before the scar is excised, and then, when the circulation of the flaps is assured, excise the scar and immediately shift in and suture the flaps. When the flap or flaps are shifted in finally and sutured over the original defect, the wounds in the normal tissue are grafted, to hasten healing.

Another method, which will sometimes give relaxation and avoids further incisions through skin is, after undercutting outward on each side as much as necessary, to make an incision from below, parallel to the length of the wound on each side, at the outer margin of the undercut area up through the subcutaneous fat without cutting through the skin, and then if relaxation is sufficient close the original wound with sutures.

Gradual Partial Excision with Closure.—The first paper on gradual partial excision was published in 1915 by H. Morestin. This most useful plastic principle is a progressive reduction in the size of a scar by successive excisions, with closure. The method depends for its success on the fact that the skin beyond the lesion has a tremendous stretching capacity, especially when the stretching is done slowly.

After determining the amount of tissue to be removed, the area is marked out. The pattern is usually made in the shape of an elongated ellipse whose long axis, in order to facilitate closure, is in the most advantageous direction; but any shaped area may be removed as long as the resulting defect may be closed by sutures. The marked out area should be cleanly excised with a sharp knife down to normal tissue, care being taken to avoid unnecessary injury to the wound edges. Some undercutting may be necessary. All hemorrhage should be checked and the wound closed with deep sutures of fine white waxed silk or cotton, to take off tension, and on-end mattress sutures of horsehair or nylon to approximate the wound edges.

After a suitable interval, several weeks to several months, depending on the situation and when the surrounding skin has stretched sufficiently, the process is repeated and again repeated at suitable intervals until the scar has been completely removed and a narrow line scar remains. The successive excisions should ordinarily be made inside the area of the scar until the final step is reached, when it may be necessary to encroach slightly on the surrounding tissue. Proceeding in this way, one finds that the final narrow scar will be little if any longer than the long axis of the original scar. The technic is simple, and there is little danger in the procedure. Before the primary and secondary operations, preliminary massage to soften and loosen tissues is advantageous. The amount which it is safe to excise at any one operation varies with the elasticity of the skin around the scar.

If carried out properly, gradual partial excision will result in a narrow scar, which may be either straight or curved or angled depending on the way in which the excisions have been made. Often it can be managed so that the final scar will lie in a natural fold. Occasionally in extensive scars it is impossible to remove it all by this method, but the size of the scar may in this way be reduced sufficiently to make a simple plastic procedure possible.

Relaxation Incisions.—As I have said before, it is a good plastic principle to excise all scar tissue completely before making a repair, but in many instances it is not practical to carry this out, and when this is the case relaxation incisions in the scar itself may be essential in order to bring about a satisfactory result.

The purpose of relaxation incisions through scar tissue is to relieve scar tension which may either interfere with growth or with function or with permanent healing or with all of these. Relaxation incisions have been most helpful to me in dealing with large contracted thick adherent scars, and also with unstable scars which are difficult to heal and which when healed frequently break down.

The contracted portion of the scar is put on the stretch, the most binding area is located and the proposed incision line is marked out transversely across that portion of the scar. If several areas are to be relaxed, they also are marked out. Then the scar is divided completely through its full depth down to normal tissue and if possible out to normal tissue surrounding the scar. Deep attachments are loosened. Relaxation incisions may be single or multiple. They may be straight, curved or angled. If the margins of the incisions are tight and the underlying tissue tends to bulge out into the wound, the incisions may be lengthened or the margins may be relaxed by radiating incisions until they are slack. On the shaft of an extremity the relaxation incisions are ordinarily made parallel with the length of the limb, but in other large scars the incisions are made across the scar pull in any needed direction.

In making relaxation incisions the tendency is always to underdo rather than to overdo, and it must be borne in mind that the relaxation must be as thorough as possible without interfering with the circulation of scar areas between the incisions.

After relaxation incisions have been made, the tissues in the defects may be ready for immediate grafting or it may be necessary to allow a few days to elapse in order to improve the circulation and stimulate granulations before grafting can be done. All types of grafts may be used to heal the defects made by the relaxation incisions. In order to conserve skin I frequently employ small deep grafts, but split (thick Ollier-Thiersch) grafts or whole thickness grafts may also be used, depending on conditions.

In very large scars one may have to proceed in stages, gaining as much as possible each time. The first incisions may be done, the defects healed by skin grafting, and later further relaxation in other portions of the scar may be carried out in the same way. After several months have elapsed, other relaxation incisions may be done if necessary, sometimes across those made previously or in the direction not indicated at the first operation. In the thick heavy scars after relaxation incisions have been made it will be found that in time the relaxed scar tissue, although it may originally have been hard and rigid, will soften and change its characteristics so that it will be usable in the final result.

Z-Plastics.—In the contracted scar where there is a prominent scar band, bridge or web, or a scar groove, with fairly lax tissue on each side, the Z-plastic is of great use and up to the present time has been used extensively by only a few surgeons. The name is given to the method because the outline of the incision is roughly that of a Z. The maneuver will be considered here in its simplest form.

With the scar bridle or groove under tension, the proposed incisions are marked out. The central line of the Z is laid down along the most prominent part of the bridle in the selected length. Then the arms of the Z, which are of the same length as the central line, are laid down at each end of the central line on

the opposite sides and at an angle of about 60 degrees to it, and they should be parallel to each other.

When the incisions are made along these lines, two broad based triangular flaps are formed whose bases are opposite each other. These flaps are undercut and completely mobilized. They are then transposed so that their outer margins approximate and the tips of the flaps touch the outer corners of the bases of the opposite flaps. The edges are then sutured with interrupted or on-end mattress sutures of nylon or horsehair. The sutured wound is also Z-shaped, but the Z is turned through about 90 degrees, is elongated, and the central line of the original Z lies transversely across the scar pull. The actual amount of relaxation varies between 50 and 100 per cent of the length of the central line of the Z.

By Z-plastics, scar contractures may be relieved by the utilization of scar tissue. The success of the method depends on the presence of slack tissue on each side of the scar band or groove. By its use, in many instances, skin grafting or flap shifting may be avoided, and it is one of the most generally useful plastic procedures.

Skin Grafts.—A skin graft is a free transplant. The technic of obtaining the various types of skin grafts is so well known that I will not go into it here. Grafts may be grouped into thick grafts, which include small deep grafts, and whole thickness grafts (Wolfe-Kranse grafts), half thickness or split grafts, which are really thick Ollier-Thiersch grafts, and thin grafts, which include true Reverdin grafts and true Ollier-Thiersch grafts, both of these grafts being composed of the epidermis with the tips of the papillae of the corium. In other words, the tiny Reverdin and the larger Ollier-Thiersch grafts are as thin as they can possibly be cut.

Another type of skin graft, which is sometimes used to fill out depressed scar areas, is the cutis or dermal graft. It contains all the components of the skin except the epidermis. The size of the graft required is marked out on the donor surface, and then every particle of the epidermis with the papillae of the corium is removed. The remaining portion of the corium is either completely dissected away from the fat or a small amount of fat may be left attached, and this tissue is then used to fill out the depressed area. It is usually placed in an undermined pocket and should be spread out and held with sutures in position in the bed prepared for it. The process may be repeated in a few months if the filling out process has been insufficient.

The type of graft used after excision or after the relaxation of burn scars depends on the area to be grafted or varies with the choice of the surgeon. In my work I seldom use either the Reverdin graft or the true Ollier-Thiersch graft in covering operative defects made in burn scars, as these grafts are too thin for stable repair.

In many clinics the so-called split graft or dermatome graft, which is a thick Ollier-Thiersch graft, is the only type of graft used for covering practically every raw surface, either granulating or freshly made. This is unquestionably a very useful type of graft and I frequently use it, but it should not be used on every occasion even if it can be easily cut with a Padgett-Hood dermatome. I find small deep grafts most useful especially in grafting relaxation incisions in regions covered by clothing, and I also frequently use whole

thickness grafts on such areas as the face, the hands, the feet and in other exposed positions.

Skin Flaps.—A skin flap is a mass of tissue which is attached at some portion of its periphery or base by a pedicle through which it receives its blood supply, and it can be shifted only as far as its pedicle will allow.

A skin flap is made up of the whole thickness of the skin with as much of the subcutaneous tissue as may be desired and is used for the repair of those areas which, in order to obtain a resistant elastic healing, require thicker tissue than simple skin grafting will supply.

There are three basic methods of using flaps, and innumerable modifications of each method:

1. The French method of advancing or sliding flaps from adjacent tissue after undercutting. In this there is little if any twisting of the pedicle.

2. The Indian method, in which the flap is obtained from neighboring tissue and is placed in its new bed by more or less twisting or rotating the pedicle.

3. The Italian method, in which the flap is obtained from a distant part, say the arm. The pedicle may or may not be twisted.

Flaps may have a single pedicle, or the pedicle may be double. The flap may be transferred to its new bed immediately after it is raised, or the transfer may be delayed, which means that in order to assure its circulation some time may be allowed to elapse between the formation of the flap and its transfer. The flap may be placed directly on the defect prepared for it, in one stage either at once or after a necessary delay. The transfer may be in more than one stage in those instances in which, on account of the distance of the defect from the tissue chosen to fill it, it becomes necessary to grow that tissue into another part and subsequently carry it on that part to the defect. Flaps may be carried in this way almost anywhere on the body. The area from which a flap is raised may be closed by sutures, or, if this is not possible, the defect may be skin grafted.

There are certain scars, which may be excised and which cannot be closed by suture, and where, for instance on the face, a skin graft would be unsatisfactory on account of color or the possibility of subsequent pigmentation. In these cases the repair may often be most satisfactorily made by the rotation of flaps of skin and the required amount of subcutaneous fat from adjacent tissue.

In the repair of any part which has been lined with skin or mucous membrane by means of a pedicled flap, it is necessary in order to prevent future scar contraction to line with epithelium the portion of the flap which is to replace this part. In order to accomplish this the flap may be folded on itself in one of several ways, or the portion to be used may be grafted with skin or mucous membrane, as the requirements may be.

The tubed flap is probably the most generally used of the delayed transfer double pedicled flaps. It was devised by Filatoff in 1916 and independently by Gillies in 1917. The method of its formation is well known.

TYPES OF SCARS

"Pain" is a symptom which may be found in every type of scar but which fortunately is fairly unusual in old scars. Burn scars may be painful, and the pain in certain instances is sufficiently severe to cause loss of function or to incapacitate the patient even though the scar may be quite small. Larger scars of all types may also be painful, but in these cases it is often possible

to demonstrate localized points of hypersensitiveness, either single or multiple. The pain may be caused by inflammatory changes, by scar pressure on nerves or by the formation of neuromas on the small skin nerves. I have seen cases in which the pain in the scar increased in intensity as time went on, but more often the pain tends to become less severe with time and ultimately may cease as the scar matures and softens, so a period of observation is advisable before radical treatment is indicated. The treatment is simple and effective. If the painful scar is small, it should be completely excised and the wound accurately sutured. In the larger scars the painful point or points should be carefully plotted out, and then these areas should be completely excised down to normal tissue, preferably in the shape of an ellipse, and the wound closed with sutures. Sometimes a single painful point may cause the entire trouble in a large scar, and complete relief will follow excision.

Depressed Scars.—Depressed scars following burns are usually the result of third degree burns in which there has been considerable loss of tissue. The basis of all methods of dealing with depressed burn scars, when excision is possible, is excision with closure of the soft parts in layers to fill out the defect.

Some depressed burn scars are adherent to underlying tissues such as muscle or bone and, besides being objectionable in appearance, cause pain, deformity and interference with function. If possible these scars must be completely excised and the defect repaired by closing the soft parts in layers or by flap shifting. When the scar is long and narrow and depressed and adherent, as they are sometimes seen on a leg or arm following a steam radiator burn, the deeper portion of the scar may be used as a buttress over which skin and subcutaneous tissue is closed. This is the method of Poulard, and I find it most useful. The scar is outlined with an incision, which is carried down to normal tissue, and the margins are undercut. The epithelial surface of the scar inside the outlining incision is carefully dissected off, and then the tissues beyond the scar, which have been undercut sufficiently, are advanced over the scar buttress with deep sutures of waxed white or black fine silk or cotton, and the skin is closed with on-end mattress sutures of 4.0 or 5.0 single filament nylon, or with horsehair. This will eliminate the depression and result in a narrow unobjectionable normal level scar.

After the excision of a depressed scar, which can be closed by suture, it is sometimes necessary, in order to fill out the depression, to roll in flaps of adjacent subcutaneous fat whose pedicles are either below or are attached to the skin itself. These are advanced and sutured into proper filling position, and then the skin is closed.

If a depressed scar is large and cannot be repaired after excision by closure of the adjacent soft parts, it may be necessary to bring in a pedicled flap of skin with sufficient subcutaneous fat either from adjacent tissue or from a distant part to fill the defect. Another method is to make a delayed transfer double pedicled flap of skin and subcutaneous tissue and shift the tissue from one or both sides of the defect into the defect, thus filling it out. If the lateral defects cannot be sutured, a split or whole thickness graft may be used. If the depressed scar is large, soft and movable it may be improved by gradual partial excision, by rolling in pedicled flaps of adjacent subcutaneous fat, by undermining and inserting a fat and fascia graft or by inserting a dermal graft. In suitable cases autogenous carti-

lage or preserved icebox cartilage cut to pattern or diced, as suggested by L. A. Peer in 1943, may be used to fill out a depressed scar of reasonable size. In my experience the use of foreign bodies or paraffin for this purpose is contraindicated.

Extensive smooth (skin level) scars may follow burns on any part of the body and, when they are soft and movable, are frequently best left alone, especially if they are in inconspicuous situations. Should removal be desired, one or more of several methods may be employed: excision followed by skin grafting; the shifting in or the rotation of a flap of skin and subcutaneous tissue; gradual partial excision.

Large, thick contracted adherent scars are a common type and may present difficult plastic problems. They are often of long duration and may vary in thickness from that of the normal skin to 2 to 3 cm. or more. They may be found in any location on the body and may be completely healed, the surface, especially in the thickest portion, being covered with a scaly horny material, and these areas tend to crack open from time to time. In other instances, even after many years, there may be one or more chronic ulcerated areas on the most contracted portion of the scar which have never healed, and sometimes malignant degeneration may take place in these areas.

Contracted scars often seriously interfere with function and in the growing period check development or distort the involved portion of the bony framework. If they occur after the growing period has passed, then the lack of function caused by the scar contracture on such bones as the humerus or femur will sometimes cause atrophy from disuse.

These scars may be very extensive, and it would be poor surgical judgment in many instances to attempt complete excision because of the impossibility of obtaining sufficient skin to cover the defect made by the excision. In these cases the use of relaxation incisions is the method of choice as the relaxed scar between the incisions, when it changes its character, can be utilized in the final healing.

Unstable scars are those which usually follow extensive loss of the whole thickness of the skin and are most frequently found in cases in which the tissue losses involve the entire circumference of a limb or a large area over the vault of the cranium. These are in most instances too extensive to consider complete excision. The healing in the majority of cases has been by cicatrization, but sometimes the condition follows inadequate or unsuccessful grafting.

The scars are paper thin and are very unstable and may be entirely healed one day and, without apparent cause or following very slight trauma, on the day following may ulcerate in many places. The history is slow healing and then breakdown, and this may go on for years, during which time the patient may be completely incapacitated.

The first paper on the use of relaxation incisions followed by skin grafting in the treatment of unstable scars was published by J. S. Davis in 1917. It has been my experience that this is the only satisfactory method of dealing with this type of scar.

The method is as follows: The incisions should be marked out and should extend the entire length of the scar into the normal skin above and below it and should expose normal tissue even if necessary to go through the deep fascia. Many of these unstable scars are on legs and arms, and the incisions in these cases should not be made immediately over bone. For a leg

or an arm or thigh, three incisions running parallel to the length of the limb are usually sufficient. The incisions may or may not go through the ulcerated areas. After the relaxation incisions have been made, the ulcers on the scar tissue between the incisions rapidly heal, and the scar itself changes its characteristics and becomes stable and strong. The wounds made by the incisions may be grafted immediately if the tissues are ready for grafting; otherwise after a few days, when the granulations have formed, the grafting may be done. I use small deep grafts or thick Ollier-Thiersch (split) grafts for grafting the relaxation defects, depending on the conditions.

Keloidal Scars.—It is difficult to differentiate the thickened, hard, red, tender, itching painful type of keloidal scar, which not infrequently follows burns, from a true keloid, and doubtless many of them are true keloids. Be that as it may, this type of scar sometimes follows burns, particularly those caused by chemicals, and it is a particularly difficult type to treat. Up to this time no specific treatment has been devised. Sometimes carefully given x-ray or radium therapy will blanch out and soften these scars and make them more comfortable, but frequently this type of treatment is unsatisfactory. These scars are often found on the backs of the hands, on the ears, on the cheeks and on the neck, the chest and the trunk. They usually follow burns which have destroyed the full thickness of the skin and which have been slow in healing. Why they occur in some burns and not in others, or why they occur in some areas on the same patient and not on others, although the healing has apparently been the same, I do not know. If the keloidal scars are not causing loss of function, time and plenty of it should be allowed to elapse before attempting any operative procedure.

In keloidal scars of reasonable size, for years I have been giving preliminary irradiation and then by the process of gradual partial excision removed the scar, keeping the sutures always in the scar area and in time finishing up with a comparatively narrow scar. Irradiation is also given each time after the sutures have been removed. Whether the preliminary irradiation does any good or not is a matter of question, but I have continued to use the method with fair satisfaction. In large areas on the face and hands excision with skin grafting or flap shifting may be necessary, but the results cannot be counted on. Complete excision with closure is usually followed in the true burn keloid by a bigger and better keloid. Removal by the endotherm followed by irradiation is sometimes done, and successes have been reported. Capillary drainage is usually unsuccessful. In fact, there is no completely satisfactory treatment of this type of scar.

REGIONS

As burn scars and deformities are found on all parts of the body, it might be helpful to consider different regions and briefly to mention methods which might be useful in the treatment of some of the lesions in these regions. As these scars may vary in each case and in each location, the methods are offered simply as suggestions, as each case must be studied out individually as to the best method of repair. In all of these operative cases much help can be obtained by the proper use of suitable immobilizing dressings and appliances, which should secure the part in the desired position in comfort and at rest.

Head.—Scalp: Burn scars of the scalp are at times very difficult to deal with. If the scar involves a large part of the scalp, is thin, is unstable and is tightly stretched on the skull, sometimes "tunnel grafts" of whole thickness or split thickness skin are effective in starting lines of stable skin. At other times relaxation incisions, with grafting of the defects thus made, promise the best result; in other instances removal of the scar with skin grafting, either split or whole thickness, depending on the conditions. When the scar involves only a portion of the scalp and a considerable amount of hair bearing skin remains, it is often possible to shift pedicled flaps of this hairy skin into strategic areas of the scar and thus make it easier to cover the hairless scar with a better arrangement of the hair.

In the midst of extensive old burn scars of the scalp, masses of closely adherent necrotic bone may be found. In these cases the bone should be removed down to normal bone or, if it includes both tables, down to the dura, and then the repair should be made. A slower method is to bore numerous holes through the bone to allow the formation of granulations and then, when the granulations have formed, to graft.

Forehead: Contracted burn scars of the forehead, with or without scalp involvement, will often cause abnormal raising of the eyebrows and even of the eyelids themselves. In order to overcome this, a relaxation incision completely through the scar is made at the selected level transversely across the forehead from one temporal region to the other, the tissues are loosened and into the defect thus made a single whole thickness graft or thick split graft is sutured. In suitable cases the scar may be completely excised and the defect filled by a whole thickness graft or a thick split graft. If a scar in the temporal regions is hairless and unsightly, a flap of hair-bearing skin may be brought forward successfully from the scalp back of the ear to relieve conspicuous baldness in front of the ear.

Eyelids: Frequently ectropion of one or both eyelids, on one or both eyes, due to burn scar contractures occurs. In my experience, thin hairless whole thickness grafts are to be preferred, either from the normal upper lid, from the inner side of the upper arm or from the prepuce. Thick split grafts may be used, however. Adhesions should be made between the lids at several points to put them on the stretch before the grafts are sutured into position. Sometimes a flap from the temporal region or forehead is to be preferred for the repair of the lower lid. Eyebrows and eyelashes are often destroyed by burns and cause pronounced disfigurement. After the contractions are relieved these can be replaced by transplanting free grafts or pedicled flaps of hair-bearing skin by special technics. The complete restoration of eyelids and also the formation of sockets for artificial eyes is necessary in certain severe burns, and this may be accomplished by the use of suitable flaps and grafts.

Ears: Burn scars of the ears vary greatly. The cartilaginous framework may be practically intact and covered with a thin adherent scar. In other instances there may be every grade of cartilage destruction. Sometimes the lobule of the ear is fused with the scar on the adjacent portion of the cheek. The cartilaginous framework may be completely embedded in scar and closely adherent to the skull. In some instances simple relaxation with Z-plastics or skin grafting may be all that is required, but in others the complete recon-

struction of the external ear is required, with cartilage transplantation, skin grafting and flap shifting as may be necessary in each case. Keloidal scars are not uncommon on ears and, after considerable time has elapsed without improvement, should be excised and accurately grafted with split thickness grafts.

Cheeks: Contracted burn scars of the cheeks are frequently found, and often the scar will involve the eyelids and mouth as well. In repairing such deformities the contracted scars must be completely removed in order to relieve the contractures, and the repair made by means of large whole thickness grafts or of flaps from a distant part or by the rotation of skin from the neighborhood if such skin is not infiltrated with scar. Usually when these contracted scars are excised there is a defect of varying depth left and it is inadvisable to use a split graft, as it is not thick enough. Sometimes the whole cheek must be reconstructed, and in these cases a lining must be provided for the flap with which it is done.

Nose: Many deformities of the nose result from burns, and the repair presents a considerable problem, as frequently the skin of the forehead and adjacent cheeks is also involved in the scar. In many instances a forehead flap, either lined or unlined as may be necessary, presents the best means of making the repair, as the skin of the forehead matches the nose in color quite well. Sometimes a flap from the arm is prepared and transferred, or a flap from the abdominal wall is grown onto the hand or wrist and then brought up to the nose. When flaps are unnecessary I frequently use a free graft from the skin on the back of the ear, as this matches in color better than the skin from other portions of the body. Cartilage may also be necessary in repairing deformities of the nose due to burns, and this material may be autogenous rib cartilage, which is to be preferred, or preserved icebox cartilage may prove useful. The cartilage may be implanted into the flap some time before it is turned down on to the nose, or it may be put in after the flap has grown into its new position.

Mouth: The most common deformity of the mouth due to scar contracture is ectropion of the lower lip, and this is usually associated with burn contractures involving the chin and neck. The relief of this type of contracture calls for either whole thickness grafting or, in suitable cases, thick split grafts or flap shifting. Another deformity caused by scar contracture is the so-called "pucker string contracture" around the mouth. When the patient opens the mouth there may be one or two or even three lines of scar pull running from the nasolabial folds on each side downward and across the chin, and frequently this scar also involves the upper lip. The best procedure to relieve this condition is by Z-plastics at strategic points. Another deformity of the mouth due to burn scar contracture is microstomia. In some instances the opening between the lips has contracted down to pencil point size, and the problem of feeding the patient is a serious one. In these cases the opening is enlarged along the normal lip level to a little more than normal mouth size, the mucous membrane is sewed to the skin or remains of the vermilion border, and the angle of the mouth on each side is made with a flap of skin or mucous membrane.

In cases in which the burn has destroyed the angle of the mouth on one side and the adjacent portion of the cheek and there is a contracted scar, it is neces-

sary to reconstruct that portion of the cheek with a lined flap and incidentally to make that side of the mouth of normal size. Sometimes it is necessary to reconstruct both lips as well as the soft parts of the chin. In such cases lined flaps must be brought in to furnish the required tissue. Scar contractures involving the angles of the mouth, displacing them either too high or too low, may be corrected by Z-plastics.

Remarkable illustrations of the use of double pedicled flaps of scalp in the repair of burn defects of the face have been shown, but to my mind in most instances the procedure is poorly thought out.

Neck.—Burn contractures of the neck are quite common. They may be massive and obliterate the entire contour of the neck and chin, or they may be scar bands or bridles. Frequently the angles of the mouth, the chin and the lower lip are also involved in these scars. In the massive type the scar should be excised as thoroughly as possible, the head extended and the defect filled with a whole thickness graft, a thick split graft or with a flap, often from the back. Sometimes a broad double pedicled flap may be slid up from the lower part of the neck or the upper part of the chest. It is necessary sometimes in these cases to relieve the condition in stages. In the scar band type, Z-plastics offer the best solution, and by the use of this method skin grafting or flap shifting may be avoided.

Trunk.—Burn scars and contractures are quite common on the trunk and vary greatly in their type. The extensive contracted scar which involves the anterior part of the chest and abdominal wall frequently prevents the patient from standing erect. The shoulders may be drawn toward each other, the breasts may be drawn close together, and the patient is held in a round shouldered position. In these cases the problem is not the removal of all the scar area, which in most instances is impossible (although some of the most objectionable areas may be excised), but to produce relaxation so that the body may assume an erect position without hindrance. Relaxation incisions should be made where necessary and the defects grafted with small deep grafts or any other type of graft selected by the surgeon, a considerable portion of the scar being utilized in the final repair. If the scar is comparatively small it may be either completely excised and the wound closed or excised with grafting, or, in suitable instances, gradual partial excision is the method of choice. It is not unusual to have a scar drawing the breasts toward each other. In some of these and in other areas, Z-plastics are effective. We quite often see keloidal scars on the back, the chest and trunk, and these should be treated by methods already mentioned. Sometimes unstable scars may be found on either the front or the back of the trunk, and in these cases relaxation incisions with grafting is the method of choice.

Upper Extremity.—*Axilla:* Frequently associated with burn scars of the trunk one finds the axillary regions also involved in the scar contractures. The involvement of the axilla may vary between a shortening of the anterior or posterior axillary fold to complete obliteration of the axilla and sometimes the fusion of the arm to the chest wall. When these adhesions are of long duration, separation of the arm from the chest wall must be done carefully as the humerus, through atrophy of disuse, may become brittle and, if moved too rapidly or without great care, may be fractured by the manipulation.

In the reconstruction of the axilla, small deep grafts should not ordinarily be used, but either large split grafts or whole thickness grafts or, if suitable adjacent tissue is available, pedicled flaps should be used. Tubed flaps are also very useful in certain cases. In certain webs involving the axilla, Z-plastics are of great use.

Arms and Hands: Many burn contractures are found on the arms and hands. The joints may be involved and immobilized in abnormal positions. The contractures may be as constricting bands or grooves in the midst of reasonably good skin, or the whole extremity may be involved and function completely lost. Many of the contractures around joints cause flexion deformities, and on the hands hyperextension with subluxation is often seen. Around joints the scar must be removed and replaced by a flap or graft as seems best. All types of flaps may be used. On hands, one frequently finds the part literally "frozen," there being practically no voluntary motion of any kind possible. Sometimes dense keloid growths will form on the hands. All of these problems are difficult to overcome. Excision with replacement with flaps of various kinds or with whole thickness grafts or thick split grafts must be done. Special splints designed for the special cases are of great assistance and should be used when required. Fingers and adjacent portions of the hand may be completely destroyed by the original lesion and the stump covered by a thin, painful scar. In such cases excision and covering with a flap or graft is indicated and, if possible, the readjustment of the stump for practical use.

Unstable scars are not unusual on the arms and forearms. Here, as always where this type of scar presents, thorough relaxation incisions with skin grafting is the method of choice. In relaxing scar bands on the entire upper extremity, including the hand, Z-plastics are of great use.

On the palms after excision of scar, whole thickness grafts or thick split grafts should be used. When flaps are used, care should be taken that there is only sufficient subcutaneous fat for the purpose required and that the flap fits fairly accurately.

Sometimes the reconstruction of tendons is necessary in old burn scars on the hands. Skin and subcutaneous tissue must first be supplied and then, through this, tendon reconstruction may be made in suitable cases.

Lower Extremities.—Burn scars and numerous consequent deformities are often found on the lower extremities. These contractures may cause flexion of the thigh on the abdomen and the leg on the thigh and often cause complete loss of function. In some of these cases areas are found in the midst of dense scar which have never completely healed. Often the scar involvement will extend from the chin to the knees. I have found that relaxation incisions with grafting is by far the most useful and effective method of handling these scars. One should gain as much as one can at the first operation and later do further relaxation and more grafting. In this way the best ultimate results may be obtained. In dense old burn contractures in the popliteal space it is advisable to divide the scar transversely as deeply as is safe, then to apply traction by an orthopedic appliance and gradually stretch out the tissues, and then make the repair with a graft or flap. In this way the muscles, vessels and nerves which have contracted on account of position are gradually stretched without injury. Unstable scars on the lower extremity are also treated by long relaxa-

the patient was very toxic. The respirations were much increased and labored (40 to 60 per minute). She was extremely pale, and there was slight icterus of the scleras. The face was slightly swollen. She complained, however, only of pain in the left flank. The heart sounds at the base were just audible but were of fair quality at the apex, where a soft systolic murmur was heard. The rhythm was regular, the rate very rapid. There was dullness in both lower lung fields posteriorly, with patchy areas of bronchial breathing and bronchophony. Crepitant rales were also heard here. Abdominal examination revealed a slight distention, with pronounced tenderness and spasm in the left flank and costovertebral angle. The spleen was palpable 2 fingerbreadths below the left costal margin and was exquisitely tender. The liver was questionably palpable. Pelvic examination was essentially negative, except for a slight foul discharge.

whole blood. During the following two days the patient's temperature ranged between 101 and 105 F. and was spiking in character. She was no longer in shock. The blood pressure was 100/60. The pulse rate was 120 and no longer thready. On the afternoon of January 7 the patient's arms, anterior chest and lower eyelids were covered with petechiae, which appeared in showers. The eyegrounds did not show any embolic phenomena. On that day she became irrational and had four convulsions lasting about one minute each and occurring at two to three hour intervals. Sedation was obtained with soluble barbitol, and hypertonic dextrose solution was administered intravenously.

About half an hour before the fourth convulsion, penicillin was started intravenously (100,000 units in 1,000 cc. of cooled isotonic solution of sodium chloride). This was followed by another 100,000 units of penicillin administered in the same

Clinical course. * Penicillin started January 8 at 12:20 a. m. Patient had four convulsions in seven hour interval between permission and delivery of drug. A, 1,500 cc. of 5 per cent dextrose in saline solution intravenously. B, 1,500 cc. of 5 per cent and 1,500 cc. of 10 per cent dextrose in saline solution intravenously.

X-ray examination of the chest on Jan. 3, 1944 revealed evidence of consolidation of both lung fields extending out from the central areas.

Blood cultures taken on January 3 and 5 were positive for *Staphylococcus aureus*. Urinalyses taken during this period (all catheterized) showed persistent albuminuria, a trace to 4 plus, occasional to many red blood cells per high power field, specific gravity 1.007 to 1.012, and occasional epithelial cells. The blood was of type A, Rh positive, red blood cells numbered 3,120,000, hemoglobin was 75 per cent, 13 Gm., white blood cells numbered 12,800 with neutrophils 82 per cent, lymphocytes 18 per cent and mononuclears 2 per cent. The blood Kahn reaction was negative. The icterus index January 2 was 11. The blood sulfathiazole level was 12.8 January 7. On the 5th the blood urea was 13, creatinine 1.6. On the 7th the white blood cells numbered 5,050, with 85 per cent neutrophils and 13 per cent lymphocytes.

The diagnoses established at this time were *Staphylococcus aureus* septicemia, bilateral bronchopneumonia, peritonitis and toxic hepatitis.

Chemotherapy was stopped on January 5 and oxygen was administered, as well as another transfusion of 500 cc. of

manner. Both doses were given at a rate of 40 drops per minute. This was followed by 1,500 cc. of 10 per cent dextrose in isotonic solution of sodium chloride intravenously. Penicillin was continued intramuscularly, 20,000 units in 4 cc. of cooled isotonic solution of sodium chloride every three hours. Another transfusion of 500 cc. of whole blood was given on January 8 and 500 cc. of blood plasma was administered on the 9th. The temperature dropped to a normal level on the 9th but the pulse rate remained considerably elevated. On the 10th penicillin was reduced to 10,000 units intramuscularly every three hours. On the 12th the patient showed improvement clinically, becoming quite rational, and was now able to take fluids by mouth. The petechiae faded within forty-eight hours. The signs in her lung fields diminished, and oxygen was no longer necessary. The abdominal distention decreased; the liver was no longer palpable, but the spleen was still two fingerbreadths below the costal margin and tender. Unfortunately the supply of penicillin was finished on the 12th. At this time a peripheral and sacral edema developed and now a diastolic gallop was heard for the first time along the left sternal border.

On January 10 the white blood cells numbered 9,400, with 84 per cent polymorphonuclears and 13 per cent lymphocytes.

Blood urea nitrogen was 77, creatinine 18 on the 11th. Blood cultures on the 9th and 13th were negative. The icterus index was 11.3, serum bilirubin 1.3, blood protein 6.8 per cent, cephalin flocculation test 2 plus. January 12 urinalysis showed 4 plus albumin, specific gravity 1.020, urobilinogen positive in 1:20 dilution, negative in 1:40. An electrocardiogram revealed regular sinus rhythm, low voltage in all complexes, inverted T_1 interpreted as indicating myocardial damage. Chest x-ray examination on the 13th revealed congestion and exudative infiltration in both central zones and bases. No pleural fluid was seen, there was no change in the cardiac outline.

The patient was placed on a low protein salt free diet on the 13th and fluids were restricted to the preceding day's output. Only on January 10 did the urinary output fall below 1,000 cc. On the 14th a new supply of penicillin was received, and this was given intramuscularly 15,000 units in 3 cc of cooled isotonic solution of sodium chloride every four hours for five days and continued for five more days at the rate of 10,000 units every four hours. This course was completed on January 23. Another transfusion of 500 cc of whole blood was given on the 22d. The edema had almost completely subsided by this time except for a slight amount over the dorsal surface of the feet. The blood urea had fallen to 11. The abdomen was now soft and the spleen, while still palpable, was only slightly tender. There were still signs of a resolving pneumonia in both lower lobes.

The picture was complicated on January 22 when the patient complained of moderate pain in the left chest in the posterior axillary line. This pain was aggravated by inspiration. Examination revealed flatness in the extreme left base with diminished bronchial breathing and diminished tactile and vocal fremitus in the same area. An x-ray examination of the chest on the 24th showed evidence of a small amount of fluid at the left base and a slight increase in the size of the cardiac shadow. On the 26th a thoracentesis was performed for diagnostic purposes and 200 cc of straw colored fluid was withdrawn. This was later found to be sterile.

The gallop rhythm disappeared on the 29th but a soft to and fro friction rub was heard along the left sternal border for two days, February 3 to 5. At the same time it was noted by x-ray examination that the heart measured approximately 15 cm in its transverse axis.

During this time the temperature ranged between 98 and 101 F. The patient improved from day to day and the blood cultures were persistently sterile. On February 1 for the first time the temperature was normal the entire day and remained so thereafter. She was allowed to sit up on the 10th. Physical examination and radiography revealed the heart contour to be normal in size and both lung fields clear and completely expanded. The abdomen was soft and the spleen was just palpable but not tender. The patient's appetite was good and the urinary output was normal. The electrocardiogram of February 14 showed all T waves to be upright and the QRS complexes to be normal except for slight slurring of the R wave in leads I and 3. The patient had a normal menstrual period starting February 15, which lasted four days. Pelvic examination revealed uterus anterior and a small cervical os with a slight erosion. The adnexal regions were slightly thickened and tender. When the patient was sufficiently strong, having been up and about eleven days without complaint, she was discharged on February 21 to a convalescent home. She will be followed closely in the medical and gynecology clinics for a period of six months or more.

Final laboratory examinations revealed white blood cells 9,700 with 64 per cent polymorphonuclears, 30 per cent lymphocytes, 4 per cent eosinophils and 2 per cent mononuclears. Hemoglobin was 62 per cent, 8.9 Gm. Red blood cells numbered 3,140,000, the color index was 0.95. The specific gravity of the urine was 1.006, with 30 to 40 white blood cells per high power field (noncatheterized), 1 plus albumin and many squamous cells.

COMMENT

This case presented a staphylococcal septicemia arising from a uterine focus, which up to the present day has been a fatal one. Additional interest was found in the development and treatment of the different complications which occurred. These were, in the order of their occurrence, peritonitis, toxic hepa-

titis, bilateral bronchopneumonia, acute glomerulonephritis, toxic myocarditis, left pleural effusion and pericarditis with effusion.

The question arises as to the role of penicillin in the treatment. There is no doubt in the minds of the men who followed the case that without penicillin it would have been fatal. It is felt that the patient was moribund when penicillin was started. The rapid decline of the temperature in the first twenty-four to forty eight hours following the initial dose of penicillin, accompanied by the seven negative blood cultures and the subjective as well as the objective improvement of the patient, were directly attributed to the drug. The low grade fever which persisted for three weeks later was due to the multiple complications resulting from the profound sepsis that was present before the blood stream could be made sterile. In this type of infection one must expect to find, as we did, almost every system involved. The course of penicillin was prolonged not because we thought that the drug would have a direct effect on each site of trouble but because we felt that penicillin would maintain a sterile blood medium and thus prevent further spread of infection should the organisms persist in embolizing from the primary focus. At the same time the already involved sites, i. e. lungs, kidneys and heart, were treated as indicated.

Besides appreciating the effectiveness of penicillin we also learned, and it cannot be stressed too strongly, that supplemental therapy in these cases is absolutely essential for successful management. Optimal nutrition and the use of all supportive means at our disposal play a most important role. This patient had six transfusions of whole blood and one of plasma, as well as several infusions of dextrose in saline solution intravenously and oxygen when needed. A thoracentesis was performed also in an effort to prevent further complications. Liver, iron, vitamins and diets according to the condition of the patient were used for the purpose of keeping up the body's natural defenses.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and other agents of the National Research Council.

SYLVATIC PLAGUE

The role of fleas in the transmission of *Pasteurella pestis* was not established experimentally until 1898, when Simond¹ succeeded in transmitting the disease from a rat dying of plague to a healthy rat by means of fleas. He thought that the infection resulted from inoculation of infective feces into the bite wound. Ten years later Verjbitski² observed that many species of rat fleas do not bite human beings but that they do cause fecal contamination of clothing or may be crushed and their intestinal contents rubbed into skin punctures or abrasions. This early theory of fecal transmission was first challenged by Walker,³ who showed that when tuberculin, vaccine lymph or staphylococcus emulsion is rubbed over recent flea bites inoculation does not follow.

Bacot and Martin⁴ found that two species of rat fleas were able to transmit plague during the act of sucking under conditions that precluded possible infection with dejecta. Considerable proliferation of the plague bacillus was detected in the digestive tract of many fleas, often sufficient to cause a blocking of the lower end of the esophagus. As a result of this blockade, regurgitation of micro-organisms takes place when the fleas attempt to feed on a new host. Bacot and Martin believed that only fleas suffering from this temporary obstruction at the entrance of the stomach are responsible for insect transmission of this disease.

Douglas and Wheeler⁵ of the Hooper Institute, University of California, have recently repeated this work, using *Dipodomys montanus*, one of the commoner fleas on California ground squirrels, as vectors, with *Xanthopsylla cheopis*, the classic rat flea, as control. The white mouse was selected as the experimental animal in place of the guinea pig, used by most previous investigators. The white mouse was found to be susceptible to intraperitoneal inoculation with a relatively

small number of *Pasteurella pestis* organisms. So inoculated they develop a relatively high bacteremia, distributed evenly throughout the peripheral blood stream. The degree of bacteremia was determined for each animal by microscope counts and plate counts, the average obtained by the two methods seldom differing by more than 15 per cent.

A number of previously unfed, laboratory reared fleas were placed on a plague infected mouse whose *Pasteurella pestis* bacteremia had been previously determined. Five minutes after having been fed, each flea was thoroughly emulsified in a known volume of sterile distilled water. The resulting aqueous extract was plated on agar and the viable *Pasteurella pestis* count determined. From this count the volume of the blood meal was readily calculated, which volume usually varied from 0.015 cmm. to 0.050 cmm., with an average of 0.030 cmm. per flea. The average number of organisms ingested with each meal was 300,000 when the fleas fed on a mouse with 2,000,000 *Pasteurella pestis* organisms per cubic millimeter of its circulating blood.

The Indian Plague Commission⁶ first pointed out that a certain proportion of fleas are able to clear themselves of the ingested bacilli. The rate of this autopurification was determined by the California investigators. By the end of forty-eight hours 40 per cent of the plate counts showed a considerable multiplication of the ingested organisms in the rat flea, while 60 per cent of the plates showed a slight reduction in the viable count. Only 2 per cent of the rat fleas showed complete autopurification. In the squirrel flea multiplication of the ingested bacteria was demonstrated in but 20 per cent of the cases, with complete autopurification within twenty-four hours in 60 per cent of the insects. Confirming this relative rate of autopurification, it was found that after a single infectious meal and subsequent daily feeding on normal mice 24 per cent of the squirrel fleas and but 4 per cent of the rat fleas had lost their power to transfer the infection. The mechanism of this autopurification has not yet been fully determined.

Serial microsections showed that within two days after ingesting septicemic blood plague bacilli may be seen in small clumps in the stomachs of squirrel fleas. By the tenth day both stomach and prementriculus are packed solidly with a bacterial mass now extending into the esophagus. In this condition the flea becomes infectious. The period of infectivity, however, is usually short. If allowed to feed once each day, the flea will transmit the infection two or three times but will almost invariably die on the fifth day, death presumably being due to starvation. In the rat flea development of a similar esophageal blockade usually required sixteen days, the flea usually dying four days later.

Daily plate culture made of the vial of each flea showed that only 56 per cent of the daily fecal samples from the squirrel flea and but 25 per cent of the samples from the rat flea contain viable *Pasteurella pestis* organisms. The average daily count in these positive cultures was 200 bacilli, with the number frequently falling to less than 10. Even assuming that the fecal bacteria are of full virulence, this number is usually too small to incite an infection in a guinea pig by the cutaneous or subcutaneous route. Moreover, Bacot and Martin found that these fecal bacteria are usually of low virulence since they are more readily phagocytized than control bacteria from the blood stream of plague infected rats.

Demonstration that within twenty-four hours 60 per cent of the infected squirrel fleas are able to digest or otherwise free their alimentary canal of *Pasteurella pestis*, and that the remaining 40 per cent become infectious only between the tenth and fifteenth day is contrary to prevailing clinical belief based on the historical theory of fecal transmission.

CHEMOTHERAPY OF MURINE TYPHUS

Since the beginning of the present war the possibility of successful chemotherapy of rickettsial infection has been subjected to intensive clinical research. Various sulfonamides¹ have been tried with alleged success in cases of human typhus. Their usefulness, however, appears to be limited to the treatment of pneumonia and other secondary bacterial invaders. Neoarsphenamine in metaphen,² atabrine-plasmochin and atabrine-calcium mixtures³ have also been given with allegedly favorable results. The available evidence, however, is too scanty for a definite conclusion.

In order to make possible a study of a larger number of therapeutic agents with adequate controls, Peterson⁴ of the International Health Division of the Rockefeller Foundation has begun a study of the chemotherapy of murine typhus. This is a rickettsial infection of mice first described about four years ago by Gildermeister.⁵ Yolk sac cultures of the infectious agent usually contain a sufficiently large number of rickettsias to kill mice by toxic action within two to eight hours after intraperitoneal injection. By reducing the dose, however, the mice are not affected by the toxin but die four to five days later of rickettsial infection. Peterson selected as his standard dose 0.5 cc. of a 1:100 dilution of murine infected yolk sac injected intraperitoneally. This usually killed from 80 to 100 per cent of all control mice. A group of 20 mice was usually used in testing each chemotherapeutic agent, with an equal number of

untreated controls. Feeding of each test drug was usually begun about twenty-four hours before intraperitoneal inoculation. With other groups the therapeutic feeding was begun at the time of the inoculation or delayed from twenty-four to seventy-two hours after inoculation.

Among the drugs thus far tested, toluidine blue has given the most promising results. In a typical experiment 40 mice were fed fox chow containing 1.5 per cent toluidine blue. Twenty-four hours later these mice together with 20 normally fed controls were injected intraperitoneally with the standard dose of murine infected yolk sac. The mortality was 80 per cent among the untreated controls but only 29 per cent in the group fed toluidine blue. In other groups a 90 per cent control mortality was reduced to 25 per cent by feeding 0.5 per cent toluidine blue beginning at the time of the infection, with a reduction to 50 per cent in a parallel group in which the therapeutic feeding was not begun till twenty-four hours after inoculation. If the therapeutic feeding was delayed till the forty-eighth hour, toluidine blue was without demonstrable effects. In partial explanation of these results it was found that 1:10,000 toluidine blue had a definite in vitro neutralizing action on the yolk sac toxin and also reduced the infectious titer.

Less effective therapeutic activity was noted with "forbisen." With this product it was necessary to increase the concentration to 2.5 per cent in the diet in order to produce significant results. In a typical experiment approximately 60 per cent of the infected mice survived when fed 2.5 per cent forbisen, while 100 per cent of the control mice died of the infection.

The discovery of two effective chemotherapeutic agents against rickettsial infections is promising, stimulating hope of an eventual successful chemotherapy of human typhus.

PHANTOM LIMBS

"Phantom limb" was described as early as 1551 by Ambroise Paré and later by S. Weir Mitchell. Revival of interest now is due to war casualties and to realization that phantom limb is a common occurrence after amputations. Leriche observed its occurrence after amputations in 98 per cent, Pitres in 97 per cent, Weir Mitchell in 95 per cent and Foerster in 100 per cent. Riddoch¹ states that it is usual for the patient to experience sensations following amputation, at least for a time, as if the limb were still present, and the proportion is greater with upper than with lower limbs. These sensations may be painless or painful but are always more or less abnormal. Bilateral amputations may be followed by bilateral phantom hands or feet; or one or both may be absent; or one may be painless

1. Riddoch, George: *Phantom Limbs and Body Shape*, *Brain* 61: 197 (Dec.) 1941.

and the other painful. Intractable pain in the phantom limb, while relatively rare, may present a formidable therapeutic problem. The pain appears about the same time as the phantom, immediately or some time after the operation, and is felt mainly in the hand or foot. In the hand pain is referred chiefly to the wrist, palm, knuckles and tips of the fingers and thumb, and in the foot to the instep, heels and toes. If there had been a painful wound in the forearm or leg before the amputation, the pain may seem to persist in the same area in the phantom as if the sore were still present. The sensations experienced in the phantom are those of warmth, itching, burning, throbbing, piercing, cramping, sticking or cutting. The pain is usually continuous and subject to exacerbations. There may be a sensation of the phantom limb being crushed or torn. Many patients ultimately become narcotic addicts or are driven to suicide. The posture of the phantom part is almost invariably that of the limb before amputation, especially if pain was antecedent to operation.

The supposition that the condition is psychogenic in nature and that the patient is a psychoneurotic has not been borne out by clinical observations. Early observations, particularly those of Weir Mitchell, pointed to the important role played by the peripheral nerve stumps. Mitchell observed that faradization of the brachial plexus in a patient long after amputation reproduced the sensation of hand which was bent and hurt the patient. He concluded that irritation of sensory trunks may produce impressions of muscular motion in the sensorium. According to Riddoch the phantom sensation is a projection arising from the postcentral sensory association areas in the cerebral cortex. He attaches considerable importance to the condition of the stump, especially of its peripheral part. Certain features of the stump, which may appear sooner or later after the operation, influence the late development of pain in the absent part. End bulbs or neuromas are invariably present in amputation stumps. They may be small and benign or abnormally large and tender. The nerve trunks may become affected and be the seat of interstitial neuritis. The worst cases of painful phantom limbs tend to become associated with these abnormalities in the stump. Any stimulus, physical or emotional, that can evoke pain is usually effective for both stump and phantom limb. Then cramplike rigidity of the phantom hand and fingers most often forms the most constant background of pain. Pain in the phantom is due to excessive stimulation of the nerves in the stump and results in extended representation of the absent limb in the phantom and limits voluntary movement of the phantom only because voluntary effort aggravates the pain. The prevailing posture of the phantom is that of the part at the time of amputation. "It is as if the postural model had become frozen when normal stimulation ceased."

The part played by the autonomic nervous system was emphasized by Leriche and by Livingston.² Repeated injections of sympathetic ganglions produced in some of their cases of painful phantom limb beneficial effects which persisted for weeks or months. Experimental evidence is against the opinion that pain impulses from the periphery traverse the sympathetic ganglions. They probably follow the mixed nerves to enter the spinal cord by the posterior roots of the brachial plexus. The best that can be said for this therapy is that the symptoms may be temporarily alleviated in a number of instances, and that occasionally the relief afforded by such an injection persists for a long time (Livingston). Resection of painful neuromas, in the opinion of Leriche and of Bailey and Moersch,³ never produces lasting results, as the neuroma invariably reforms. White⁴ feels that the removal of a palpable painful neuroma is worth a single trial, provided the pain disappears when the neuroma is injected with procaine. Repeated excisions of neuromas, neurectomies, reamputations at higher levels and resection of posterior roots consistently fail and should not be resorted to. Chordotomy is more effective than section of the posterior roots. Bailey and Moersch state, however, that this operation has not afforded relief in cases observed by them.

The observation by Head and Holmes that a contralateral cerebral lesion abolished the phantom at once in a patient observed by them called attention to the role of the higher centers in the mechanism of this phenomenon. Gutierrez-Mahoney⁵ argued that, since the peripheral pathways are multiple, it would be simpler to interrupt the chain at the intermediate level by removal of the corresponding part of the postcentral cortex. He has performed this operation on a man aged 40 who got his right hand caught in a circular saw, which amputated the terminal phalanx of the middle finger and the terminal and half of the middle phalanx of the ring finger. Immediately after operation he was conscious of the presence of the amputated fingers. These phantoms were extremely painful. Gutierrez-Mahoney exposed under local anesthesia the left parietal lobe, determined by stimulation the area corresponding to the middle and ring fingers of the right hand, and excised this area by subpial resection. There was an immediate disappearance of the phantom fingers and the pain, which had not recurred two years after the operation. This new type of intervention may prove to be the solution of the problem of the intractable pain of the phantom limb.

Current Comment

IMMUNE SERUM GLOBULIN FOR MEASLES MADE AVAILABLE TO CIVILIANS

Elsewhere in this issue (page 638) appears an announcement relative to a plan adopted by the American Red Cross in cooperation with the armed forces and with various pharmaceutical manufacturers to make available at cost to the American people surplus immune serum globulin to be used for the prevention of measles. From its very inception this has been a fine example of efficient functioning of the democratic way of life. The research leading to the development of this product was carried out by the Plasma Fractionation Laboratory of the Harvard Medical School under Professor E. J. Cohn. The work, both laboratory and clinical, was supported by contracts from the Committee on Medical Research of the Office of Scientific Research and Development and with guidance by the committees of the Division of Medical Sciences of the National Research Council. The medical departments of the Army and Navy gave the product efficient trial in various installations. The quality and production are under control of the National Institute of Health. The blood was contributed by millions of American citizens in the depots established and maintained by the American Red Cross. Five pharmaceutical manufacturers processed the material and have agreed—since the blood is donated by the people—to make the product available through health departments at actual cost. No doubt many additional uses for surplus material from the blood thus procured will be developed. Already experimentation is turning to the surplus corpuscles and to other protein fractions. Eventually, no doubt, in the postwar period means will be found for adjusting the present tremendous program to peacetime civilian and military needs. The plan now established by the American Red Cross and the participating private agencies is highly commendable.

BAGASSE DISEASE OF THE LUNGS

Bagasse is the product remaining after the extraction of sugar from sugar cane. According to Sodeman and Pullen¹ this material is commonly baled and if not used immediately may remain exposed in the field for some months before being converted, by processing, into insulating and acoustic board. Workers employed in the breaking of these bales sometimes acquire a respiratory illness, 7 cases of which have been previously reported. This paper presents 11 additional case reports with resultant clarification of the clinical picture. Cough and dyspnea were early and important symptoms. Dyspnea occurred in all cases and was almost invariably the chief complaint. It appeared suddenly and became sufficiently severe to force the

patient to rest. Cough occurred in all instances, and hemoptysis was noted four times; it lasted only a few days and the amount varied but never exceeded a teaspoon daily. In general, the sputum which was raised in 9 instances was scanty and mucoid. Pharyngeal irritation was noted in 3 cases; pleural pain was not observed, but retrosternal pain was associated with dyspnea and cough. Night sweats, chills and fever were not infrequent. Intermittent fever with temperatures ranging from 99.8 to 101.2 F. was observed and persisted up to three or four weeks. In 3 cases fever was not noted. Tachycardia occurred in 4 cases. Weakness over a long period was characteristic. Examination of the chest revealed nothing spectacular, although impaired resonance and diminished breath sounds were noted in 4 instances. Roentgen examination of the chest showed in all cases a milky mottling throughout both lungs, most dense in the hilar areas. Leukocyte counts varied from 7,400 to 20,600, and 10 of the 11 patients had counts above 10,000. In 7 cases the differential count revealed polymorphonuclear leukocytosis. Treatment consisted of rest in bed during the acute stages of the disease and palliative medication. The hospital stay varied from nine to ninety-three days. Needle biopsy specimens were obtained from the lung of 1 patient in the sixth and seventh weeks of the disease. Microscopic studies of these specimens indicated the presence of bagasse dust with a severe and unusual cellular reaction, the nature of which has not yet been established. The condition described is a true industrial disease.

ACADEMIC FREEDOM AND MEDICAL EDUCATION

If recent proposals to supply federal funds in large quantities to educational institutions after the war are adopted, the effect will influence the future of medicine for decades. F. R. Moulton, writing in the May bulletin of the American Association for the Advancement of Science, raises some important points bearing on this problem as far as it relates to higher education in general and to academic freedom in particular. Many of his points are especially cogent for medical education. "Naturally an institution facing an acute emergency," Moulton says, "will not be unduly strict in grading students on whose return its future seems to depend. At the end of the second year (of federal support) a continuing emergency will call for a third year, and then the colleges and universities will have been added to the long list of pressure groups receiving sustenance from Washington." Many questions would be better raised now rather than later. If medical students receive federal largess, will not the government be entitled to some service in return, and if so what? Should the young doctor spend one year, two years or more in repaying his debt to the state? Is the medical school which is dependent for its existence on federal funds obligated to the federal government? And if so in what way must its debt be paid?

1. Sodeman, W. A., and Pullen, R. L.: Bagasse Disease of the Lungs, *Arch. Int. Med.* 73: 365 (May) 1944.

aided greatly in maintaining the morale and fighting strength of its men. It is with great pleasure that I express my appreciation of his service and commend him for his performance of duty." Dr. Shulman graduated from Syracuse University College of Medicine in 1935 and entered the service in May 1942.

Colonel Irwin Bradfield Smock

The Legion of Merit Award was recently presented to Col. Irwin B. Smock. The citation accompanying the award read as follows: "From Feb. 18 to April 25, 1942, as medical inspector, Hawaiian Department, he rendered meritorious acts of extraordinary fidelity and service in establishing and coordinating the operation of expanded medical department installations in the Territory of Hawaii. Through his able planning and supervision of construction, the military hospitalization program on the island of Hawaii was greatly expedited, and installations were prepared for immediate occupancy and use when hospital units arrived to furnish hospitalization for incoming tactical units." Dr. Smock graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1912 and entered the service April 27, 1938.

Lieutenant James B. Ashley

Posthumous award of the Bronze Star medal has been made to Lieut. James B. Ashley. He was killed in action at Guadalcanal, Jan. 13, 1943. The citation accompanying the award states that "he placed the welfare of those injured above his own safety and gave his life in the pursuit of his duties." Dr. Ashley graduated from the University of Michigan Medical School, Ann Arbor, in 1941 and entered the service July 1, 1942. His father, Lieut. Col. L. Byron Ashley, is now with the Harper Hospital Unit in Italy.

MISCELLANEOUS

SURPLUS IMMUNE SERUM GLOBULIN FOR MEASLES (NORMAL SERUM GAMMA GLOBULIN [HUMAN])

Measles Immune Serum Globulin (Normal Serum Gamma Globulin [Human]) Declared to Be in Excess of the Requirements for the Armed Forces Now Released for Civilian Use

Immune serum globulin (normal serum gamma globulin [human]) is a by-product in the processing of a blood substitute; namely, serum albumin. It is derived from the blood contributed by our citizens through the American Red Cross. The laboratory and clinical research leading to its development were supported by the Committee on Medical Research of the O. S. R. D. and by the Division of Medical Sciences of the National Research Council. In processing the blood there is built up a surplus of immune serum globulin (normal serum gamma globulin [human]) beyond the needs of the armed forces. As far as is practicable it is desired that this surplus should be returned to civilian use. The processing of the serum globulin from the time it is separated from the albumin until it has been placed in the final container and tested for safety, purity, sterility and potency involves, however, a considerable processing expense. This expense is an unavoidable part of the processing and must be covered in some way before the globulin can be made available for civilian use. The method of meeting this charge is to be patterned after the procedure now used by the Army and the Navy for covering the cost of processing plasma and albumin; namely, having the cost assumed by the agency receiving and distributing the material. The plan proposed is as follows:

1. Under the existing contracts between the Navy and the several processing laboratories, the Navy has control over the disposition of the crude globulin fraction which is derived as a by-product from processing serum albumin. From time to time the Navy will declare as surplus any amounts of crude globulin which are not needed by the armed forces and will assign to the American Red Cross the disposition of these amounts.

2. The control of processing and the testing and release of the product should be, as under the Navy contracts with the several

FROSTBITE AMONG AMERICAN COMBAT AIRMEN GREATLY REDUCED

Brig. Gen. Malcolm C. Grow, surgeon chief of the Air Service Command, recently announced that frostbite among American combat airmen has been reduced 1,500 per cent in one year. The chief factors in this tremendous reduction are improved electrically heated flying clothing, face masks, gloves and the new windows for waist gunners aboard fortresses and liberators. General Grow stated that "in April 1943 60 men out of every 10,000 flying operationally suffered frostbite, which in many cases resulted in amputations and permanent injuries to the victims. Today, thanks principally to the waist window, which reduces wind blast 90 per cent, that figure has been slashed to 4 in 10,000." Of 131,000 combat crewmen flying in operations during April 1944, only 56 were hospitalized for frostbite.

SPECIALIZED WOMEN WANTED FOR ARMY

An opportunity is now open for certain specially trained women to serve with the Medical Department of the Army in the Women's Auxiliary Corps. The following are some of the positions open to qualified women who may be enlisted for service with the Medical Department: pharmacists and pharmacists' aides, orthopedic mechanics, laboratory technicians, x-ray technicians, lip reading technicians, braille technicians (instructors), occupational therapists and aides, dental laboratory and hygienist technicians and dental aides. Interested persons should apply to the local officer of the Procurement Service or to the WAC recruiting office.

processing laboratories, by the Plasma Fractionation Laboratory of the Harvard Medical School until such time as the constancy of the product as produced by each commercial firm has been satisfactorily demonstrated. As this product is a biologic preparation, it must first be released by the National Institute of Health before the producing laboratories can supply it to the various agencies.

3. The American Red Cross will enter into an agreement with the several processing laboratories as to the delivery price f. o. b. the processing laboratory of a 5 cc. vial of the finished, refined and packaged concentrated globulin. This price is to be a cost price, based on the allowable factors necessary for processing this material without profit from the crude globulin state to its finished form.

4. Each vial shall bear the label required by the National Institute of Health for licensed products. Each cardboard container for individual packaging shall bear the same and also the following statement:

"This product was obtained from blood donated by volunteers through the American Red Cross for the armed forces. It is a by-product of serum albumin and is hereby returned through the American Red Cross for military or civilian use free of charge. The cost of processing, testing and packaging was paid by the agency distributing the product. The resale of this material is prohibited."

5. The American Red Cross will provide each processing laboratory with a list of participating agencies which are entitled to receive the immune serum globulin (normal serum gamma globulin [human]). The following agencies and they alone in the order of preference will be eligible:

- (a) The armed forces of the United States.

- (b) The American Red Cross, the United States Public Health Service, and any other agency of the U. S. government whose order for the product is approved by the Red Cross.

- (c) State departments of health and those local health departments whose orders are approved by the Red Cross.

These departments may on request furnish immune serum globulin (normal serum gamma globulin [human]) to any

hospital within their jurisdiction at the cost to them. This will not constitute a resale of the product. The cost shall not be passed on to the patient, either directly or indirectly.

6 The American Red Cross makes this announcement simultaneously to the participating agencies and to the public, and it will be further disseminated through joint action with the Association of State and Territorial Health Officers.

7 Participating agencies may purchase as many 5 cc vials of immune serum globulin (normal serum gamma globulin [human]) as they need. However, in order to insure equitable distribution with respect to these agencies and to the several laboratories, all requests for this material shall be filed with and approved by national headquarters of the American Red Cross. National headquarters, on the basis of the stocks of dried serum globulin available in the several laboratories and geographic consideration of conveniences and expense, and irrespective of the contract price, will in turn inform the requesting agency with which laboratory the order should be placed, and in this the decision of the Red Cross shall be final. The Red Cross will also send to the designated laboratory or laboratories a copy of its instructions to the requesting agency. The purchase price of the laboratory plus any shipping charges, shall be borne by the agency placing the order.

8 Each processing laboratory will provide the American Red Cross monthly with an inventory of the amount of dried and stored immune serum globulin (normal serum gamma globulin [human]) and the amount fully processed, tested, packaged and ready for distribution together with a report of the number of finished packages distributed during the previous month. In turn the American Red Cross will send to each laboratory monthly a compilation of said inventories and reports received from the laboratories.

9 Each agreement between the American Red Cross and the processing laboratories may be terminated by mutual consent or at the option of either party on the submission in writing of notice to such effect sixty days prior to such proposed termination. The disposition of any stock of serum globulin in any form remaining in the hands of such processing laboratory on such termination shall, for a period of six months after the effective date of termination, be subject to the control and direction of the American Red Cross in accordance with the provisions of this plan, thereafter, such remaining stocks may be disposed of by the processing laboratory at a price not to exceed the price agreed on plus reasonable costs of sale and distribution based on the previous years' experience of the processor in the sale and distribution of other biologic products.

CIVIL SERVICE COMMISSION'S CLEARANCE PROCEDURE FOR SENIOR CADET ASSIGNMENT

The U S Civil Service Commission recently established the following clearance procedure for senior cadets requesting appointment to one of the five federal services. This report was made to a representative of the Division of Nurse Education which administers the U S Cadet Nurse Corps under the United States Public Health Service. The commission acts only as a pool for the five federal hospital services—Army, Navy, U S Public Health Service, Veterans Administration and Indian Service—to clear applications of prospective senior cadets. A check is made by the commission to see that the school of nursing is approved by state boards of nurse examiners. Applications are then sorted according to the student's preference and are filed on cards. At present, representatives of each of the federal nursing services go to the Civil Service Commission headquarters to review applications of their service.

A cadet's eligibility is determined by the federal service to which she has applied. Each service makes its own selection, the scholastic standing of the cadet being a major deciding factor with each service in accepting the cadet's application.

Physical requirements regarding height, weight, teeth and vision also must be met. If a cadet nurse does not meet the requirements of her first choice her application is returned to

the commission, where it is referred to the service of her second choice. Should the cadet's application not be accepted by any of the services, the School of Nursing is notified and the application is returned to the Civil Service Commission stating the reason for rejection.

Miss Ruth A. Heintzelman was recently appointed nursing consultant, Medical Division of the U S Civil Service Commission. She is also nursing consultant on the clearance of senior cadet nurses. As of May 1, 1944 the commission had processed approximately 3,000 applications. Out of this number approximately 2,000 had been turned over to the five federal services. The Army decided on 799, the Navy accepted 534, the U S Public Health Service accepted 21 and the Indian Service accepted 31.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service.

(Continuation of list in THE JOURNAL June 24, page 562)

MASSACHUSETTS

Union Hospital, Fall River. Capacity, 186, admissions, 3,829. Miss Jennie F. Smithies, R.N., Superintendent (2 interns, October 1).

MINNESOTA

Bethesda Hospital, St. Paul. Capacity, 180, admissions, 6,083. Rev. L. B. Benson, Superintendent (interns).

NEW YORK

Coney Island Hospital, Brooklyn. Capacity, 300, admissions, 5,611. Dr. Saul M. Penner, Superintendent (2 interns).

CIVILIAN AMBULANCE SERVICE

Civilian ambulance service may soon become serious, particularly in those sections of the country where bad roads are accelerating normal wear, members of the Ambulance Body Manufacturers' Industry Advisory Committee of the War Production Board informed officials of WPB's Automotive Division recently. A substantial need for ambulances in industrial plants already exists. Discussion of the possibility of manufacturing new ambulance bodies on used chassis led to the conclusion that such a program would be difficult in view of the acute shortage of used chassis, but industrial members expressed the belief that the conversion of used passenger cars into ambulances would be the only practicable way to ease the present shortage when conditions justified such a step. Discussing the relation of the ambulance industry to the automotive industry and preparation for the reconversion period, industrial members expressed the view that no independent planning was possible. Any ambulance plans must wait on the plans for the automotive industry as a whole, members of the committee said.

DRUG SUPPLY DEPOTS ESTABLISHED IN EIGHT MAJOR PORTS

The War Shipping Administration recently announced the establishment of drug supply depots in eight major ports, which will assure a supply of essential drugs for men in the American Merchant Marine. Supplies of penicillin, dried blood plasma, insecticides and quinine will be maintained in depots at the ports of New York, Portland, Ore., Seattle, New Orleans, Norfolk, Va., Baltimore, San Francisco and Philadelphia. This will enable the operators of all WSA owned or chartered vessels to maintain readily a supply of essential medicines as prescribed in the minimum drug list. Preparations such as these are not always available in quantity on the open market, and the cooperation of the War Production Board and the armed services was established in setting up the WSA depots. Supplies will be allocated from the depots to operators on an actual cost basis.

STATE MEDICAL OFFICERS OF SELECTIVE SERVICE SYSTEM HOLD MEETING

State medical officers of the Selective Service System opened a three day meeting June 5 at national headquarters. Major Gen. Lewis B. Hershey, director, delivered the address of welcome and Col. Leonard G. Rowntree, chief of the Medical Division, presided at the sessions which were devoted to discussions and reports on medical phases of administering the Selective Training and Service Act. Vice Admiral Ross T. McIntyre, Surgeon General of the Navy and chairman of the five man commission on physical standards, addressed the meeting Monday. Major Gen. Norman T. Kirk, Surgeon General of the Army, spoke Tuesday, and Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, spoke on Wednesday.

DEDICATE NEW NATIONAL INSTITUTE OF HEALTH IN HAVANA

On May 17, at the invitation of the Cuban government and Dr. Alberto Recio, the minister of health, Brig. Gen. James Stevens Simmons, chief, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, visited Havana and took part in the dedication of the new National Institute of Health. During the ceremonies President Batista decorated General Simmons with the medal of the Carlos J. Finlay National Order of Merit in the grade of Gran Oficial. The President also sent by General Simmons to Major Gen. Norman T. Kirk, the Surgeon General of the Army, a certificate conferring the Carlos J. Finlay Order of Merit in the grade of Gran Cruz on the former American Yellow Fever Commission for its fundamental experimental work in Cuba on the etiology and transmission of yellow fever under the leadership of Major Walter Reed. The certificate will be preserved in the Army Medical Library in Washington.

MINNESOTA GRADUATES IN MEDICAL CORPS TO RECEIVE BULLETIN FREE

All graduates of the University of Minnesota Medical School who are officers in the medical corps of one of the services are eligible to receive, without charge, the Bulletin of the Minnesota Medical Foundation. The mailing list is known to be incomplete and to contain inaccurate addresses, especially as regards the Navy Medical Corps. All Minnesota graduates who are officers in the Army or Navy are invited to send their service address to the editor of the Bulletin, 132 Medical Sciences Building, University of Minnesota, irrespective of whether some issues of the Bulletin have reached them.

MORE LACTOSE AVAILABLE TO PENICILLIN PRODUCERS

Because of the threatened shortage of lactose, important for the growing of the mold that yields penicillin, steps have been taken by the War Food Administration in cooperation with the producers to double last year's lactose production in 1944. The output of lactose this year is expected to reach 14 million pounds. The War Production Board estimated that penicillin manufacturers will need 6 to 7 million pounds annually.

WARTIME GRADUATE MEDICAL MEETINGS

The following speakers and subjects have recently been announced for Wartime Graduate Medical Meetings:

At the U. S. Naval Hospital, Santa Margarita Ranch, Ocean-side, Calif.: Differential Diagnosis of Functional and Organic Heart Disease (panel discussion), Dr. James F. Churchill and Dr. Wilbur Beckett, July 12.

At the U. S. Naval Hospital and U. S. Naval Academy Dispensary, Annapolis, Md.: Drug Allergies, Dr. Nathan B. Herman, July 21.

PUBLIC HEALTH UNDER HITLER

In addressing chemists of Lower Silesia in Breslau, the reichsapothekerfuhrer stressed that no difficulties with regard to the supply of raw materials need be feared, as all genuine military and civilian requirements of medicine have been guaranteed, according to the *Hamburger Fremdenblatt* of February 12. The shortage which has been noticeable in some places was caused by an occasional morbid craving for medicine shown by many persons. A considerable part of the demand for medicine, which has increased extraordinarily, is the result of a real need, but medicines were often hoarded. While before the war a small packet was bought, purchasers now always buy the largest. In this way persons who really need medicine are made to suffer.

In order to prevent this, measures are to be taken, for instance, on the insulin market, which will guarantee that the requirements of genuine sufferers from diabetes are met. Naturally many prewar medicines are no longer available, but they are dispensable drugs for which there are equivalent substitutes. Raw materials have been secured. Air raids can only temporarily interrupt deliveries and the interruptions can quickly be made up for from substitute stocks throughout Germany. The demand for homeopathic medicines, which varies in different places, can also be taken into consideration. The output of the pharmaceutical industry, which has increased threefold compared with prewar years, naturally goes largely to the armed forces, but these in turn make medicines available to the raised districts and for other special needs. In Germany as a whole 11 million children are collecting medicinal herbs. Their average is estimated at 1 Kg. of dry herbs. A considerable proportion of these goes to the armed forces. The shortage of camomile this year is due to the bad harvest. The name *Deutscher Hausteek* may be used only for teas examined by the reich health office. Most of the young people have been conscripted, and therefore the shop staffs are often too old. In addition, the chemist now often has to do twice as much work. The employment of women has been justified by the results.

Curculul of Jan. 24, 1944 (Rumania) states that speculation in medicines which are in short supply, such as insulin, surpasses all limits. Although these are officially lacking in chemists' and drug stores, offers to obtain them for use as a privilege are made, naturally at high prices. It is thought that the Ministry of Health should investigate the matter.

CINCHONA BARK AND CINCHONA ALKALOIDS

The War Production Board recently amended order M-131, governing the allocation of cinchona bark and cinchona alkaloids, to permit the delivery of quinidine to an ultimate consumer on the receipt of a prescription signed by a person who is licensed to prescribe drugs. Only physicians licensed to practice medicine were permitted to prescribe quinidine prior to this revision. Quinidine may be used only for the treatment of cardiac disorders, the War Production Board said.

COMMUNITIES IN NEED OF PHYSICIANS

The following communities have applied to the U. S. Public Health Service for federal assistance in obtaining the services of physicians under the recently enacted law authorizing an appropriation of \$200,000 for the relocation of physicians:

Waxhaw (Union County), North Carolina.
Glenrock (Converse County), Wyoming.
Leola (McPherson County), South Dakota.
Faith (Meade County), South Dakota.
Vale (Malheur County), Oregon.
McEwen (Humphreys County), Tennessee.
Tribune (Greeley County), Kansas.
Colome (Tripp County), South Dakota.
Hiwassee (Townsend County), Georgia.
Slover (Morgan County), Missouri.

Physicians interested in locating in these communities should communicate with the Surgeon General, United States Public Health Service, Washington (Bethesda Station), D. C.

ORGANIZATION SECTION

PROCEEDINGS OF THE CHICAGO SESSION

MINUTES OF THE NINETY-FOURTH ANNUAL SESSION OF THE AMERICAN
MEDICAL ASSOCIATION, HELD IN CHICAGO, JUNE 12-16, 1944

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, June 13

The House of Delegates was called to order at 10 a. m. by the Speaker, Dr. H. H. Shoulders.

Roll Call

On motion of Dr. A. A. Walker, Alabama, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the House dispensed with the roll call.

Presentation of Minutes

Dr. A. A. Walker, Alabama, moved that the House dispense with the reading of the minutes. The motion was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, reported that one hundred and sixty-nine members of the House of Delegates had been registered.

Report of Reference Committee on Medical Education

Dr. W. C. Davison, Chairman, presented the following report:

1. Report of Council on Medical Education and Hospitals: Your reference committee approves the report of the Council on Medical Education and Hospitals, section by section and as a whole, as printed in the Handbook.

2. Supplementary Report of the Council on Medical Education and Hospitals: Your reference committee approves the supplementary report of the Council on Medical Education and Hospitals, which includes the "Essentials of an Acceptable School for X-Ray Technicians" and changes in the curriculum section of the "Essentials of an Acceptable Medical School."

3. Resolution Opposing Training of Nonmedical Personnel in Audiometry: Your reference committee approves the Resolution Opposing Training of Nonmedical Personnel in Audiometry, introduced by Dr. G. Henry Mundt, Illinois, amended to read: "Resolved, That the American Medical Association is opposed to the training and practice of nonmedical personnel in audiometry, except under the direction and supervision of a qualified physician."

4. Resolution on Shortage of Trained Nurses: Your reference committee approves the Resolution on Shortage of Trained Nurses, introduced by Dr. S. E. Gavin, Wisconsin, amended to read:

WHEREAS, There is a very obvious deficiency in trained personnel for nursing; and

WHEREAS, The demands for adequate nursing are apt to be greater; be it

Resolved, That the Council on Medical Education and Hospitals communicate with the various national organizations concerned with nursing for the purpose of discussing the present nursing situation in order that the proper nursing bodies may consider the matter with a view toward its amelioration.

5. Resolutions on Creation of Board of General Practice: Your reference committee does not approve the Resolutions on creation of a Board of General Practice, introduced by Dr. H. A. Luce, Michigan, because of lack of jurisdiction, but it

recommends that this proposal be referred to the Council on Medical Education and Hospitals for transmissal to the Advisory Board for Medical Specialties.

Respectfully submitted,

WILBURT C. DAVISON, Chairman.
THOMAS S. CULLEN.
CHARLES H. PHIFER.
FRANCIS F. BORZELL.

On motion of Dr. Davison, seconded by Dr. Walter E. Vest, West Virginia, and carried, section 1 of the report of the reference committee, approving the report of the Council on Medical Education and Hospitals, was adopted.

It was moved by Dr. Davison, seconded by Dr. William Weston, Section on Pediatrics, and carried, that the House approve the second section of the report of the reference committee, approving the supplementary report of the Council on Medical Education and Hospitals.

Dr. Davison moved that the third section of the report of the reference committee, approving an amended resolution referring to audiometry, be adopted. The motion was seconded by Dr. John Z. Brown, Utah, and carried.

The fourth section of the report of the reference committee, recommending an amended resolution dealing with shortages of trained nurses, was adopted on motion of Dr. Davison, seconded by Dr. James C. Sargent, Wisconsin, and carried.

The fifth section of the report of the reference committee, referring resolutions dealing with the creation of a board of general practice to the Council on Medical Education and Hospitals, was adopted on motion of Dr. Davison, seconded by Dr. John Z. Brown, Utah, and carried.

On motion of Dr. Davison, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, the report of the reference committee was adopted as a whole.

Report of Reference Committee on Miscellaneous Topics

Dr. H. A. Luce, Chairman, presented the following report: To this committee was referred the resolution from Dr. James R. Miller, Connecticut, which is short.

Your committee wishes to quote from "The Appeal in behalf of the Wells National Testimonial Fund," as follows: "The Benefactor of Mankind, by the bestowal upon the world of the greatest physical boon ever yet conferred by man upon his fellows—the soother of the sufferings of the battle field, the hospital and the household—perishing prematurely in the course and as a consequence of his own zealous eagerness to amplify and extend the advantages of his discovery, not only received no recompense for his labors, such as has fallen to the lot of those inventors with whom he should at least take equal rank, but left unprovided with even moderate means of support the loved ones of his own fireside."

Your reference committee wishes to add to the resolution a further recommendation that this endorsement and commendation be officially transmitted to the Wells National Testimonial Fund Committee, by the Secretary of the American Medical Association.

Respectfully submitted,

HENRY A. LUCE, Chairman.
CHARLES G. STRICKLAND.
LUCIUS F. DONOHUE.
ROBERT A. PEERS.
ROBERT H. HAYES.

Dr. Lucc moved that the report of the reference committee be adopted. The motion was seconded by Dr. Henry S. Ruth, Section on Anesthesiology. After discussion by Drs. Allen H. Bunce, Georgia, Henry S. Ruth, Section on Anesthesiology, Holman Taylor, Texas, and Dr. Luce, the report was referred back to the reference committee, on motion of Dr. James R. Miller, Connecticut, seconded by Dr. Lloyd Noland, Alabama, and carried.

Report of Reference Committee on War Participation

Dr. James R. McVay, Chairman, presented the following report, which on motions of Dr. McVay, duly seconded and carried, was adopted section by section and as a whole after discussion by Dr. Francis F. Borzell, Pennsylvania, and Dr. McVay:

1. Your Reference Committee on War Participation met and considered the printed report of the War Participation Committee in the Handbook and the remarks of Dr. Walter Donaldson, chairman of the committee, before the House of Delegates. It desires to commend the work of this committee.

The fact that but twenty states have responded to the request for the creation of special committees of War Participation leads us to reemphasize that portion of the report in order that the delegates from states not having such a committee may urge their respective state societies to create such a special committee. It seems to us that these committees may be of great help in cementing the home ties and continued morale of those in the service and those who remain at home.

Service bulletins and mimeographed letters such as those of Oregon, Ohio, Pennsylvania and numerous other state and county societies serve to keep the men in the service in active contact with their home community activities and are a most useful activity of War Participation committees.

2. War Participation committees that have secured the publication of the names of service members in local newspapers, county medical society bulletins and other such means help to acknowledge the patriotism of those of us who are in their country's service. Public exercises of service flag unveilings and of memorial plaques with addresses by local and state administrative officials help to create statewide recognition of the unselfish devotion of the medical profession toward the successful prosecution of the war effort. The voluntary enlistment of nearly 50,000 American physicians in the service of their country is a fitting challenge to those who would charge the profession with selfishness. The continued emphasis and publicity of this endeavor of patriotism now and after the war is won is a worth while activity of War Participation committees.

The protection and securing of economic and professional rehabilitation of members of the profession returning from service is a lofty ideal but can help those men only when it is translated into action. The establishment of loan funds by county societies, through the efforts of War Participation committees, can be of material assistance to returning medical veterans in reestablishing themselves in their practice and is a commendable and worthy effort.

Respectfully submitted,

JAMES R. McVAY, Chairman.
EDWARD JELKS.
JAMES P. WALL.
ANDREW F. McBRIDE.
WILLIAM D. JOHNSON.

Report of Reference Committee on Postwar Planning

Dr. Walter F. Donaldson, Chairman, presented the following report, which was adopted as a whole, on motion of Dr. Donaldson, seconded by Dr. John Z. Brown, Utah, and carried:

Your reference committee is fully appreciative of the foresight which led early in 1943 to the American Medical Association assuming the leadership in planning for postwar medical service. It recognizes the wisdom which resulted in close cooperation with the American College of Physicians and the American College of Surgeons and later with the invaluable

relationships established with hospital associations, with American medical colleges, with state licensing boards and with others.

The complexity of the problem involved is illustrated by variation in the age and in the extent of previous medical training and experience of the approximately 50,000 physicians in military service. To meet adequately the needs and the desires of these thousands on their release from duty with the Army, Navy, Public Health Service and other war related services will undoubtedly at times try the skill of the planners and the patience of the doctors anxious to return to their pre-war practice or to graduate training preliminary to entry into their chosen fields.

The good work of the Committee on Postwar Medical Service has undoubtedly been climaxed in the pilot postwar planning questionnaire mailed in February and March to 3,000 medical officers on duty with the armed forces as they were selected, 1 in every 15 names from an alphabetical machine record list of all medical officers on duty on the first of last October.

Your reference committee is informed that the first report on the findings of this generous sample group of completed questionnaires returned as they have been prepared by Lieut. Col. H. C. Lueth, Liaison Officer with the American Medical Association, is to be published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of June 24. This initial analysis will doubtless be followed by others appearing in THE JOURNAL, and the anticipated needs of the returning doctors may thus be clarified state by state to a degree limited only by the enthusiasm and energy with which state medical associations may see fit to collaborate with the postwar planning committee of the American Medical Association in this most important service to the public and our thousands of returning fellow physicians.

The Committee on Postwar Medical Service is deemed equally worthy of the full support of this House of Delegates in its recommendations for the development at headquarters of the American Medical Association of a trustworthy source of information available to all returning medical officers. These forms of advance preparation plus experience, which the Council on Medical Education and Hospitals is anxious to develop in behalf of and through the expressed needs of returned medical officers for whom the war is already over should promptly and effectively aid in delineating the extent and type of graduate instruction now desired by those who entered medical service for the armed forces at experience levels ranging from incompleting internships to the last word in specialists' training. These our colleagues are not to be forgotten, and the individual members of the 1944 House of Delegates may best implement the plan of the Committee on Postwar Medical Service by studiously reviewing each published interpretation of postwar desires as revealed by the returned questionnaires and by then stimulating postwar service committee action at state and county levels.

Your reference committee closes its report by transmitting to this House of Delegates and the great membership thus represented the cordial invitation of the Committee on Postwar Medical Service to all constantly to make use of the planning committee's facilities at headquarters of the American Medical Association in the coordination of constituent and component society endeavors to accomplish that which should be our common purpose now as always, to "promote the science and art of medicine and the betterment of public health."

Respectfully submitted,

WALTER F. DONALDSON, Chairman.
GEORGE F. LILL.
HAROLD W. SMITH.
WILLIAM A. COVENTRY.
HENRY R. VIETS.

Reference Committee on Sections and Section Work

Dr. L. W. Larson, Chairman, presented the following report, which on motion of Dr. Larson, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, was adopted:

The prominence which the annual session of the American Medical Association has maintained for many years is due primarily to the excellent scientific programs which have been presented. The Council on Scientific Assembly, with the assistance of the section secretaries, is responsible for this record of achievement and should be highly commended for its work. It is to be especially commended for the excellent program arranged for this year, in spite of many difficulties incident to the war emergency.

Your reference committee wishes to reemphasize the desirability of providing scientific papers of interest to the general practitioner in both the Section on Miscellaneous Topics and the General Scientific Meetings.

Respectfully submitted,

L. W. LARSON, Chairman.
WILLIAM WESTON.

R. D. BERNARD.

Report of Reference Committee on Hygiene and Public Health

Dr. Don F. Cameron, Chairman, presented the following report:

1. Supplementary Report of Council on Industrial Health: The Supplementary Report of the Council on Industrial Health was approved by the Board of Trustees and was referred to this reference committee for further study and recommendation. A copy of this report was given to each member of the House at the Monday session. This report was approved by the Council on Industrial Health after consultation with representatives from the American Federation of Labor, the Congress of Industrial Organizations, the National Association of Manufacturers, the United States Chamber of Commerce and the Joint Claims Committee of the Stock and Mutual Casualty Insurance Companies. Because of the current importance of placing the disabled in suitable employment, each of the listed conferees is asking for ratification of this report by the respective parent organization.

This report appeared to your reference committee to have been very well prepared. It deals concisely with the purpose, scope, general procedures, equipment and records advised in this work, together with recommendations as to the type of examinations involved and gives suggestions as to the personnel and costs and outlines a suitable procedure for review of, and appeal from, examinations and decisions.

Your reference committee recommends that the House of Delegates approve this Supplementary Report of the Council on Industrial Health.

2. Resolutions on Giving Intelligent Instruction in Science and Biology to the Youth of America and Proposed Resolutions Regarding Health Education in Secondary Schools: The Board of Trustees approved and sent on for presentation to the House of Delegates the resolutions adopted by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association. These resolutions have to do with the teaching of health education and biology in secondary schools.

In pursuance of the action of this House of Delegates a year ago, the Bureau of Health Education submitted the resolutions to the Joint Committee on Health Problems in Education of the American Medical Association and the National Education Association. The joint committee thoroughly approved the basic idea that sound teaching in hygiene is dependent on a real understanding of the fundamentals of biology involved. It emphasized its reluctance to urge this biologic instruction on the schools until there was available a teaching personnel capable of handling the subject in a really constructive way, avoiding nonessential controversial features. It outlined in some detail some subjects recommended for emphasis, such as the role of bacteria and parasites in disease, cell growth in relation to heredity and malignant disease, an accurate vocabulary in matters pertaining to sex and reproduction, and an intelligent understanding of the theories and basic facts of biologic genesis and evolution.

Your reference committee approved in general the report and recommendations of this joint committee. It thought advisable to recommend modification of one of the basic resolutions of the joint committee by inserting the phrase "with collaboration of suitable medical authorities," so that this portion of the resolution will read "The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association endorses the recommendation of the Office of Education that schools throughout the country provide, with the collaboration of suitable medical authorities, programs of health education for all secondary school students. . . ."

With this modification, your reference committee commends and endorses the outline and recommendations for the teaching of biologic science and physical fitness suggested by the joint committee.

3. Resolution on Report of Council on Medical Service and Public Relations Dealing with Tuberculosis: To this committee was also referred that portion of the report of the Council on Medical Service and Public Relations which has to do with a communication received by it from the National Tuberculosis Association requesting the Council's approval of a resolution on the control of tuberculosis. The Council approved a revised resolution as printed in the Supplementary Report emphasizing in particular "that it is necessary to extend procedures for careful, continuous supervision of the tuberculous by practicing physicians, who, in cooperation with duly constituted health authorities, federal, state and local, are in a position to deal with these problems by modern methods to prevent the spread of this communicable disease."

Your committee recommends the approval of the resolution as printed in the Council's report.

4. Survey of Centers for Diagnostic Aid to Physicians: The question of centers for diagnostic aid to physicians was considered by the Council on Medical Service and Public Relations. It recommended that surveys as to the need of such centers be made preferably by the "local communities concerned." The Council recommended that the American Medical Association should "stand ready to assist local communities" in developing these centers where need for them was established.

Your committee believes that the Council intended to state but perhaps neglected to make it clear that such surveys should be made by or in consultation with the physicians of the communities concerned and that the most valuable aid which the American Medical Association could render in the majority of instances would be to make available to qualified physicians information as to what communities these surveys showed to be in need of competent diagnostic facilities.

Respectfully submitted,

DON F. CAMERON, Chairman.
WALTER W. KING.
STEPHEN E. GAVIN.
R. C. WILLIAMS.
STANLEY H. OSBORN.

Each section of the report of the reference committee was adopted on motions of Dr. Cameron, duly seconded and carried.

Dr. Cameron moved that the report of the reference committee be adopted as a whole. After discussion by Dr. Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health, Dr. Holman Taylor, Texas, Dr. Cameron and the Speaker, it was moved by Dr. G. Henry Mundt, Illinois, seconded by Dr. Mather Pfeifferberger, Illinois, and carried, that the portion of the report referring to modification of the recommendation of the Joint Committee by inserting the phrase "with collaboration of suitable medical authorities" in one of the basic resolutions of the Joint Committee on Health Problems in Education be reconsidered.

On motion of Dr. G. Henry Mundt, Illinois, seconded by Dr. A. A. Walker, Alabama, and carried, that portion of the report of the reference committee was referred to the reference committee.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Raymond L. Zech, Chairman, presented the following report, which on motions of Dr. Zech, duly seconded and carried, was adopted section by section and as a whole:

1. Proposed Amendment to Constitution Affecting Physicians in Veterans Facilities: Your reference committee feels kindly toward recommended changes affecting the Veterans Facilities and approves in principle the suggested changes. It met in conference with representatives of the Judicial Council. The problems presented were too numerous for the committee to recommend any specific changes at this time. It recommends, however, that the matter be taken up by the Board of Trustees and that the Board report on this matter at the next annual session.

2. Proposed Amendments to By-Laws, Chapter XII, Sections 2 and 3: Your reference committee approves in principle the proposed amendments to sections 2 and 3 of chapter XII of the By-Laws of the American Medical Association submitted by the delegate from the District of Columbia. It requests that the Board of Trustees study these proposed amendments and bring in a practical solution at the next annual session.

3. Supplementary Report of Council on Medical Service and Public Relations: In reviewing the supplementary report of the Council on Medical Service and Public Relations, your reference committee approves of the portion of that report dealing with the Bureau of Medical Economics and its duties but approves only in principle that portion of the report relating to the Veterans Administration.

The report of the Council on Medical Service and Public Relations that relates to students was reviewed. Your committee approves of the proposed change and suggests that the student members consist of those medical students who are in their clinical years of study.

Your reference committee recommends the adoption of this report.

4. Proposed Amendments to the Constitution and By-Laws Dealing with Apportionment of Delegates: Two amendments were introduced which would affect the apportionment of delegates, and one of these would change the entire idea of the apportionment of delegates, suggesting that apportionment be made on the basis of population. Population is hard to estimate today because of the war, there having been a great migration of people. Relocation must be anticipated following the war, and therefore it appears that apportionment on the basis of general population is not feasible at this time.

Your reference committee disapproves of any change from the present method of apportionment.

5. Proposed Amendment to Constitution, Article 6, Section 3, Introduced at the 1943 Session and Contained in the Report of the Secretary: Since the Board of Trustees of the Association represents the medical profession as a whole rather than geographic areas, your reference committee feels that the appointment of Trustees on a geographic basis is unwise and impractical. It therefore recommends that this amendment be not adopted.

6. Report of Judicial Council: In reviewing the report of the Judicial Council, your reference committee is in complete accord with the Council's clarification of the purposes outlined in the Principles of Medical Ethics and therefore recommends the adoption of the report.

At this time your committee wishes to take cognizance of the conscientious and persevering efforts of the Judicial Council under the brilliant leadership of the Chairman, Dr. George Edward Follansbee, who has devoted many years in establishing a Council which has faithfully and patiently helped solve many important problems. Dr. Follansbee's clear thinking and judicial attitude enhanced by his unquestionable loyalty to his organization sets an example for all of us. Your reference committee therefore takes this opportunity to express its deep appreciation of his untiring efforts. Furthermore, it is its sincere wish that we may continue to have the privilege from his wealth of experience and wise counsel.

Respectfully submitted,

RAYMOND L. ZECH, Chairman.
L. G. CHRISTIAN.
HARRY V. PARYZEK.
WALTER E. VEST.
CHARLES E. MONGAN.

Report of Reference Committee on Reports of Officers

Dr. George W. Kosmak, Chairman, presented the following report, which on motions of Dr. Kosmak, duly seconded and carried, was adopted section by section and as a whole:

1. ADDRESS OF THE SPEAKER, DR. H. H. SHOULDERS

It is a pleasure to commend the faithful service of your Speaker, who has concluded six years of service in this important position. His address speaks for the devotion which he has given to the onerous duties imposed on him and constitutes an evidence of the efforts which he has expended on behalf of the Association's interests. Your reference committee is in accord with the ideas expressed in the address and commends in particular his refutation of the arguments advanced in THE JOURNAL article to which reference is made, written by a prominent advocate of socialized medicine who himself is not a physician. Your reference committee believes that this refutation deserves careful attention by the medical profession.

Your reference committee desires again to express to the House of Delegates its appreciation of the excellent service rendered by this faithful officer in presiding so efficiently over the deliberations of this body.

2. ADDRESS OF THE PRESIDENT, DR. JAMES E. PAULLIN

It is a privilege to have listened to the extremely able address of our President, and your reference committee desires to make the following comments on its principal features:

(a) Wartime Graduate Medical Meetings: It is a great satisfaction to note the extended attention which has been given to this important activity by the American Medical Association and the personal interest of the President in it. The lecturers who have given their time and effort as a contribution to the war effort are to be highly commended, and approval should be given to the decision that the Association has contributed the necessary funds for this activity in cooperation with the American College of Surgeons and the American College of Physicians. Your reference committee regards this as money well spent and agrees that this type of instruction should be carried to the smaller hospitals and other medical communities distantly removed from the larger medical centers. This activity points the way for the development of more effective postgraduate instruction in the future, and the process of decentralization involved in this type of teaching is to be commended.

(b) Postwar Planning: Your President calls attention to the necessity for developing the proper type of instruction for medical men discharged from the armed services. Your reference committee commends his suggestion for the establishment of a bureau of information in the central office in Chicago and likewise the effort to stimulate the state and county societies to establish local offices which are to cooperate with that bureau in bringing the necessary information to those who desire it. This central bureau might also serve the purpose of affording to practitioners of medicine the opportunity for location in new communities, and this matter should be given adequate publicity. It would appear desirable if this particular activity could be developed into a permanent establishment under the immediate control of the Board of Trustees. Your reference committee suggests that steps be taken to carry out the recommendation.

(c) The Supply of Medical Students: This matter is dealt with under separate resolutions which have already been given consideration. Nevertheless, your reference committee desires to stress the importance of the movement for a continuing supply of students adequate for all anticipated medical needs.

(d) Rehabilitation of the Disabled: Your reference committee desires to commend the unification and expansion of efforts in this direction and suggests that the American Medical Association should be prepared to offer its services to implement this program whenever requested.

(e) Provision of Medical Care: Your reference committee desires to call the attention of the House of Delegates to remarks of the President with reference to the necessity for formulating policies for the guidance of the various officers of the Association and the House of Delegates in dealing with all questions concerning medical care. Such a statement should note the extent to which the federal government and other agencies interested in medical service have entered various

fields and enlist the cooperation of the profession in a combined program, the fact being borne in mind, however, that the control of funds and other details should be left to the state and local agencies.

(f) **Unity Within the Organization:** This seems to your reference committee to constitute a very important item in the President's address and calls for a unanimity in whatever official action may be taken by the Association through the medium of the House of Delegates and the constituent bodies of the Association. Your committee feels that it is desirable to iron out differences of opinion as to policies and other matters on the floor of the House rather than independently, so that the spirit of unity may be observed in those great questions which involve the entire profession.

In conclusion, your reference committee desires to compliment again the present incumbent of this high office for the faithful attention he has given to his important duties and for the carefully thought out recommendations contained in his report. It bespeaks for them the well deserved attention which they merit.

3. ADDRESS OF THE PRESIDENT-ELECT, DR. HERMAN L. KRETSCHMER

Your reference committee desires to commend the outspoken address of the President-Elect and to submit the following comments:

Regarding his suggestion that the education of the public particularly in social medical questions be more freely participated in by the general practitioner and family physician, it would be well if every member of the profession would make a personal effort to explain to patients, whenever the opportunity offers or can be made, the problems with which medicine is faced, and particularly the results of governmental dictation and supervision of medical practice.

The President-Elect calls attention to the prevalence of neuropsychiatric problems in the life of the nation. This situation seems to be of great proportion, and your reference committee commends his suggestion for the comprehensive study of the mental health of our people by all branches of our profession.

Your reference committee also desires to endorse his suggestion that the Council on Medical Education and Hospitals give further consideration to improvements in the teaching of pharmacology in medical schools, particularly as this applies to prescription writing and drug therapy.

Your reference committee commends the suggestion that, in addition to the preliminary program devoted to the interests of the general practitioner, consideration be given to the recommendation that each of the special sections devote one of its sessions to the presentation and discussion of papers devoted to matters of interest to the general practitioner. The American Medical Association, among its other responsibilities, should retain as one of its signal aims the conception that it constitutes an important educational institution both for the medical profession and for the public at large.

Respectfully submitted,

GEORGE W. KOMAK, Chairman.
CARL R. STEINKE.
ARTHUR S. RISSE.
THOMAS A. PITTS.
WALTER G. PHIPPEN.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. E. S. Hamilton, Chairman, presented the following report, which, on motions of Dr. Hamilton, duly seconded and carried after discussion, was adopted section by section:

REPORT OF SECRETARY

Your reference committee has reviewed the complete report of the Secretary and commends it for its information, completeness and brevity. It recommends the acceptance of the report as presented in the Handbook.

REPORT OF BOARD OF TRUSTEES

The report of the Board of Trustees is so lengthy and exhaustive that it is possible to review only the high spots in it and to comment on and make recommendations in those

controversial questions in which the House of Delegates has not previously taken definite action or where new conditions have arisen necessitating clarification of their previous position.

1. **Income and Expense:** On first reading, the net income of the Association for the current year seems very high; but when the depreciation in equipment of the physical plant, the curtailment in the salary and expense of personnel as well as the volume of proposed new expenditures is understood, it seems advisable that a surplus should be accumulated for the lean years which may come after the cessation of the hostilities. The responsibility of the American Medical Association to returning medical officers is great and the potential expense can be large in the immediate postwar years. Accordingly, after due consideration, it is the opinion of your reference committee that the Board of Trustees should be commended for its careful financial management. Your reference committee commends the Board of Trustees for instituting group life insurance and retirement annuity plans for their employees, and your reference committee recommends the approval of this part of the report of the Board.

2. **THE JOURNAL and Other Publications of the American Medical Association:** The JOURNAL continues to be well managed and edited. Careful reading thereof will keep the subscriber abreast of scientific, economic and special wartime activities of the various governmental agencies. It is particularly encouraging to notice a gain of 4,760 in subscriptions to THE JOURNAL. The report on special journals, lending library, QUARTERLY CUMULATIVE INDEX MEDICUS, HYGEIA and the American Medical Directory show the extensive activities in the publishing field. Your reference committee commends the Board of Trustees and the editors for their fine work and recommends the approval of this section of the report of the Board.

3. **Cooperative Medical Advertising Bureau:** This bureau continues to render excellent cooperation to the state journals associated with it. Your reference committee recommends the approval of this section of the report of the Board.

4. **The Council on Pharmacy and Chemistry:** This council continues to work cooperatively with federal agencies, the American Pharmaceutical Association, the Council on Industrial Health and many other organizations. It has continued its regular publications and encouraged research by grants. It investigates new drugs, reporting its findings through ethical channels to the medical profession.

The resignation of Dr. W. C. Rose, a member of the Council for seven years, is noted with regret. Your reference committee recommends approval of this section of the report of the Board.

5. **Chemical Laboratory:** The Chemical Laboratory continues to work cooperatively with the Council on Pharmacy and Chemistry as well as with the Bureau of Investigation, governmental agencies, professional groups and manufacturers. Your reference committee recommends approval of this section of the report of the Board.

6. **Council on Physical Therapy:** Publications include the Manual of Physical Therapy and that of Occupational Therapy. The Manual of Physical Therapy is being revised. This council has given attention to artificial respiration, the education of technicians, audiometers and hearing aids, ophthalmic charts and ultraviolet radiation for disinfection purposes. Your reference committee recommends approval of this section of the report of the Board.

7. **Council on Foods and Nutrition:** This council has been active in the matter of nutritional education, working with groups of the food industry and the government. It has been concerned with nutritional research and education. Many articles have been published, and the Handbook of Nutrition has been brought up to date. Your reference committee recommends commendation of this section of the report of the Board.

8. **Council on Industrial Health:** This council shows a continuous growth in its contacts with the medical profession, government, labor, insurance companies, the National Association of Manufacturers and the United States Chamber of Commerce. Medical schools have become interested in undergraduate instruction. Attendance at the annual congresses on

Industrial Health has increased. It contemplates a certifying board in the field of industrial health. Its field of activity touches workmen's compensation, rehabilitation, nutrition in industry, industrial medical service plans and research on silicosis and burns. It has prepared a very comprehensive outline for physical outline of prospective employees, rating them under three classifications: (a) fit for all work; (b) fit for work under periodic medical review (1) with limited physical exertion, (2) in nonhazardous work, (3) with orthopedic defects, (4) with defective vision, (5) with defective hearing and (6) with neuromental handicaps; (c) unfit for work at time of examination.

The physical examination blank is very complete, but your reference committee doubts if most corporations would insist on a blood smear, examination of the eye background, sedimentation rate, chest x-ray examination and Wassermann test except for food handlers.

The outline for physical examination is excellent and complete but possibly too exhaustive to be practical.

Your reference committee recommends approval of this section of the report of the Board.

9. Report of the Bureau of Legal Medicine and Legislation: Postwar medical licensure of recent graduates who have been prevented from licensure by entry into government service should be studied and given assistance. Isonipocaine, Demerol or any morphine substitutes should be brought under federal control because of their habit forming tendencies. Lectures on medical jurisprudence should be encouraged. The enacted federal legislation to commission female physicians in the medical corps of the Army and Navy to have the same pay and allowances and to be entitled to the same rights as members of the Officers Reserve Corps of the Army and Naval Reserve with the same grade and length of service meets with approval.

Twenty-four million two thousand dollars allotted to states for obstetric and pediatric care for wives and infants of service men is not entirely satisfactory and will be reported on by another reference committee, but the sum of \$200,000 for the relocation of physicians in critical areas is apparently inadequate.

The proposals for a vastly expanded program for the construction of additional hospital facilities for veterans of World War II are proper and timely, even though more than 80 per cent of all admissions have been for disabilities not connected with service.

The laws enacted for providing for the vocational rehabilitation of veterans under the direction of the Veterans Administration and of disabled civilians under the direction of the Office of Vocational Rehabilitation in the Federal Security Agency and a bill appropriating \$26,100,000 for the medical care of recruited and migrant farm workers have progressed beyond influence but meet with approval of your committee.

Other pending legislation contemplating a codification of federal laws relating to the United States Public Health Service, a study of human nutrition and nutritional value of food, the treatment of Selective Service registrants infected with venereal disease, the employment of alien physicians by the Bureau of Indian Affairs, a permanent medical corps in the Veterans Administration and the creation of a Bureau of Vital Records in the Public Health Service seemingly require further study and investigation.

The enacted legislation to provide a nurse training program administered by the Public Health Service, for which \$52,500,000 has been appropriated to date, has already progressed beyond the point where we might be of influence or service.

The special committee created to investigate the education and physical fitness of the civilian population as related to national defense is probably already at work, and it might as well be authorized to investigate the aid available to the physically handicapped.

The proposed legislation to commission optometrists and morticians as officers of the Army and Navy Medical Corps cannot be supported by the Association for obvious reasons.

The other bills providing for medical care to the recipients of public assistance, that insecticides containing arsenic or fluorine be distinctly colored, a broadening of the Social Security Act to include employees of religious, charitable, scientific and certain other organizations and to provide postwar

educational opportunities for service personnel contain nothing evidently objectionable.

The granting of military rank to members of the Navy and Army Nurse Corps and to authorized service in the medical reserve corps to be counted for pay purposes can be supported.

A publicly supported adult education program for which federal legislation is pending seems to be of doubtful value, as this is already made accessible by local educational institutions and universities.

Compulsory health insurance has been properly opposed heretofore, and the pay as you go income tax has been adequately explained in THE JOURNAL.

A pending bill conferring jurisdiction over industrial hygiene on labor departments requires additional study.

10. Report of Bureau of Public Relations: The report of the Bureau of Public Relations is purely informative and is satisfactory.

11. Bureau of Investigation: The duties of this bureau are to collect and dispense information concerning "patent medicine," quacks, frauds, and the like, to physicians, laymen, government authorities and other organizations, and it has continued to do efficient work in regard to the subjects which came within its province. Approval of this part of the report of the Board is recommended.

12. The Committee on Wartime Graduate Medical Meetings: This committee, having organized the teaching personnel and facilities of American medicine, has mobilized for the purpose of offering advanced instruction to medical officers of the armed forces and to civilian doctors. The program is arranged so as to cover the entire nation. The plan has proved to be a success, and the splendid work of the organization demonstrates the wisdom of the American Medical Association in having initiated the idea. Commendation of this section of the report of the Board is recommended.

13. Bureau of Health Education: Notwithstanding handicaps occasioned by the war, causing lessening of the work of the bureau in 1943, still the year was a busy one demonstrating continued usefulness. The work of this bureau is most important and arduous, preparing articles for THE JOURNAL and for HYGEIA, the arrangement of broadcasting radio programs and presenting public addresses and distributing pamphlets on important medical topics for the benefit of the profession and the public. By cooperation with various organizations such as the National Education Association, Parent-Teacher Associations and other groups of similar character, the bureau has carried its important message throughout the nation. Your reference committee commends the bureau for its splendid work.

14. The Committee to Study the Problems of Motor Vehicle Accidents: This committee has shown the careful investigation of this important subject. It calls attention to the various causes that contribute to accidents, both avoidable and unavoidable. It fears an enormous increase in accidents following the war on account of deteriorated cars, the need of construction and reconstruction of highways, increase in the speed limit and the unstable nervous system of drivers who return from the war. The committee suggests that, after all, the greatest problem is neither the road nor the car but the human element. It emphasizes the hazard of drivers under the influence of alcohol and gives statistics to show that 11 per cent of drivers involved in fatal accidents were drinking. They suggest that the doctor could be of great assistance in lessening these accidents by having applicants for drivers' licenses examined by medical men to determine such physical defects as the impaired limb, poor vision and deafness, and other disqualifying conditions. It offers the suggestion that the doctor may render good service to his patient when he discovers a condition of the patient that makes it unsafe for him to drive and so advises. Your reference committee commends the work of the committee on this most important subject.

15. Communication from Members of Committee on Conservation of Vision: A communication was received from members of the Committee on Conservation of Vision. Your reference committee finds that the Committee on Conservation of Vision is confronted with so many obstacles that it cannot function until these obstacles are removed. It is therefore

recommended that the communication from members of the committee be deleted from the report of the Board of Trustees and the committee be discontinued.

16. Office of Liaison Officer: The report of the Board of Trustees on the work of the Office of Liaison Officer is approved and the services of the Liaison Officer to the American Medical Association are commended.

17. Proposed Plan of American Medical Association for Postwar Education: The proposed plan of the American Medical Association for postwar education and cooperation with returning medical officers was reviewed by your committee. A joint committee consisting of members of the Board of Trustees of the American Medical Association and members of the American College of Physicians and the American College of Surgeons as well as other agencies has had several meetings and has worked out a rather definite plan for reeducation of returning veterans, assistance in location, cooperation with medical schools for postgraduate work and a study of economic conditions throughout the United States. While the committee is not ready at this time to make a definite report, it is safe to report that the matter apparently is well in hand, that questionnaires are ready for transmission to all members of the armed forces as to what their needs are in regard to postwar assistance. Already considerable money has been spent in this work, and more has been earmarked for this service. The committee is reporting this at this time so that the House of Delegates may know that this work is under way, that the returning medical officers are being consulted as to their needs and that the Trustees of the American Medical Association are alert to the responsibilities of organized medicine to its members in the armed forces. Your reference committee recommends approval of this section of the report of the Board.

18. Bureau of Exhibits: The report of the Bureau of Exhibits is of especial interest, as it shows the scope of its activities both at the time of the annual session and throughout the current year. Its value as an educational feature is probably little understood by the profession at large, but the work of the bureau is highly commended by your reference committee.

19. Resolution Requesting Board of Trustees to Prepare a Concise Statement of Achievements of the Medical Profession for Submission to Boards of Education: The Board of Trustees feels that the intent of the resolution has been accomplished through publication of material on the achievements of medicine in practically every issue of *HYGEIA* and also through several histories of medicine which have been published recently. After careful consideration of this report it was the opinion of your reference committee that this report should be referred to either the Reference Committee on Medical Service and Public Relations or to the Reference Committee on Medical Education.

20. Report of Conference of Committee Consisting of Three Representatives Each of the American Medical Association and the American Hospital Association: Your reference committee had a rather prolonged hearing with the pathologists representing the American Society of Clinical Pathologists and members of the Board of Trustees. It recalls to your attention the agreement of 1939 between the Board of Trustees of the American Medical Association and the special committee of the American Society of Clinical Pathologists as well as representatives of the American Hospital Association and the American College of Surgeons. After careful consideration it recommends the reaffirming of the agreement of 1939, since no evidence has been offered which could serve as the basis of any alteration at this time.

Respectfully submitted,

E. S. HAMILTON, Chairman.
OLIN H. WEAVER.
J. B. LUKINS.
ROBERT E. SCHLUETER.
FRANCIS J. SAVAGE.

Section 19 in the report of the reference committee, dealing with the report of the Board of Trustees which refers to the Resolution Requesting Board of Trustees to Prepare a Concise Statement of Achievements of the Medical Profession for Submission to Boards of Education, was referred to the Reference Committee on Medical Education, on motion of Dr. Hamilton, duly seconded and carried.

The reference committee was requested to bring in a report on the Communication from the American Optometric Association and on the Legislative Recognition of Cultists, both contained in the report of the Board of Trustees as printed in the Handbook.

: On motion of Dr. Lee O. Frech, Illinois, seconded by Dr. Robert H. Hayes, Illinois, and carried, the report of the Reference Committee on Reports of Board of Trustees and Secretary was adopted as a whole.

Report of Reference Committee on Hygiene and Public Health

Dr. Don F. Cameron, Chairman, presented the following report referring to modification of the recommendation by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association:

Your reference committee recommends that the modification of the recommendation by the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association be amended to read "with collaboration of suitable medical and health authorities" instead of "with collaboration of suitable medical authorities" as presented in its report previously submitted, so that the sentence containing this phrase in the report of your reference committee as presented earlier this morning should now read "The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association endorses the recommendation of the Office of Education that schools throughout the country provide, with the collaboration of suitable medical and health authorities, programs of health education for all secondary school students. . . ."

Dr. Cameron moved the adoption of the report as amended, and the motion was seconded by Dr. John Z. Brown, Utah, and carried.

On motion of Dr. Cameron, seconded by Dr. G. Henry Mundt, Illinois, and carried, the report of the Reference Committee on Hygiene and Public Health previously presented and as now amended in this report was adopted as a whole.

NEW BUSINESS

Resolution on Simplification and Standardization of Insurance Forms

Dr. Harry V. Paryzek, Ohio, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, There is a need for the simplification and standardization of forms used by private insurance companies in obtaining information and written opinions from physicians regarding policyholders; and

WHEREAS, The adoption by insurance companies of a simplified uniform method of obtaining medical reports would produce more statistical data of greater value to insurance companies, to the medical profession and to the public health agencies; and

WHEREAS, Use of a simplified uniform method of obtaining medical reports would materially assist in alleviating some of the burdensome paper work which physicians are required to do for insurance companies and policyholders; be it

Resolved, That the Board of Trustees of the American Medical Association shall be instructed to arrange for a series of conferences between representatives of the American Medical Association and representatives of private insurance carriers with a view toward working out a mutually satisfactory plan to bring about simplification and standardization of forms needed to obtain data and opinions from physicians in the adjudication of claims.

Resolution on Consolidation of Federal Health Activities in a Single Federal Department

Dr. Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, the House of Delegates has repeatedly advocated the consolidation of federal health activities in a single federal department; and

WHEREAS, In 1936 the House of Delegates specifically recommended that any active efforts by governmental agencies to study and to take measures tending to eliminate occupational diseases should be carried out under the supervision of federal, state and local departments of health; and

WHEREAS, There is pending in Congress a bill, H. R. 4371, which provides five million dollars for use by the federal Department of Labor

for allocating to state departments of labor to initiate industrial health and hygiene programs, thus duplicating activities now engaged in by the U. S. Public Health Service and by the state departments of health; therefore be it

Resolved, That the American Medical Association hereby declares its opposition to the enactment of H. R. 4371 and reaffirms its belief that any extension of governmental activities in the field of industrial health and hygiene should be developed under the supervision and guidance of the U. S. Public Health Service and state departments of health.

Resolution on Lifting of Sex Discrimination from Young Women Desiring to Study Medicine

Dr. Emily D. Barringer, New York, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, It has been laid before this Association that a very serious crisis has arisen in the medical educational program of the United States, owing to the fact that the Army program has withdrawn its allotment to 28 per cent of the student body, leaving the larger percentage of students in the class of the physically disqualified men, group 4 F and to women. This state of affairs has been confirmed by the chairman of the Procurement and Assignment Service, who sees in the near future a possible alarming shortage of physicians; and

WHEREAS, The Congress of the United States on April 16, 1943 enacted Public Law 38, permitting women physicians to secure commissions in the Medical Corps of the Army and Navy; and

WHEREAS, There has been considerable criticism that the number of women obtaining commissions has been disappointingly small; and

WHEREAS, There are many reasons for this small number, which are revealed by a careful study of the problem, as Procurement and Assignment rulings, curtailment of privileges, insurance benefits and others; and

WHEREAS, The woman student has been ignored in the accelerated educational program of the Army and Navy, being classified with the physically disqualified men and in no way receiving monetary or other help from the government; and

WHEREAS, There are many young women who would make excellent physicians if they had not been discouraged because of the sex limitation that has been placed on them; therefore be it

Resolved, That the American Medical Association go on record as lifting sex discrimination from young women desiring to study medicine and that the American Medical Association request the government to give aid to these young women in their medical education commensurate with that granted to the young men

Resolutions on American Medical Association Legislative and Public Relations Activities

Dr. George R. Dillinger, Indiana, introduced by title Resolutions on American Medical Association Legislative and Public Relations Activities, which were referred to the Reference Committee on Legislation and Public Relations

Resolutions on Speakers' Bureau

Dr. George R. Dillinger, Indiana, presented the following resolutions, which were referred to the Reference Committee on Reports of Board of Trustees and Secretary:

WHEREAS, The demand on the medical profession for speakers to lay and professional groups on subjects both economic and social that affect the public and medical profession is exceedingly great; and

WHEREAS, It is exceedingly desirable that the headquarters of the American Medical Association maintain more definite and frequent contact with the individual state societies; therefore be it

Resolved, That the House of Delegates of the American Medical Association request the Board of Trustees, when personnel becomes available, to secure men capable of serving as a speakers' bureau on a state's basis; and further be it

Resolved, That personnel be secured also to work with the Secretary of the Association in maintaining contacts with the constituent state societies.

Presentation and Address of Vice Admiral Ross T. McIntire

Dr. James E. Paullin, President, introduced Vice Admiral Ross T. McIntire, Surgeon General of the United States Navy, who addressed the House as follows:

Mr. Chairman, Dr. Paullin, Members of the House: It is always a privilege to come back here, especially when we have such a representative group from American medicine as we have in Chicago today. I think it has been too bad that we haven't been able to do this more in these past two years, but in spite of the transportation difficulties I think what we shall gain from the meeting this year will be of such tremendous value for the services that we won't mind congesting the trains and taking up a few of the spaces of some of the people who may think that they should have them.

I am very glad to have an opportunity to come before the House of Delegates and to say just one word of appreciation for the way that you people have been carrying on the work

in civil medicine. It is high time that we in the governmental services were giving much more serious thought to your problems, and that is one thing that I hope will also come from this meeting here in Chicago: what we can do to be helpful in the coming years, in these years when we shall be able to cut down the size of the medical requirements, and how we can best release medical personnel to such communities to take the load off the overworked men who are there now, especially the men in the older group. I feel very deeply about this and I can assure you that the Navy will do everything possible to help there.

We too are tremendously interested in this proposition of keeping the medical schools going. You have heard a great deal about that from your own officers. I am going to follow with the keenest interest the work that goes on in the committees and in this body in the recommendations that will be made, and not only recommendations, but we must have a follow through on this subject. The military services will need more doctors, but the civilian side of this country will need doctors much more than we in these next ten years, and so it is a very serious thing, one of deep concern to every one of us, that this subject is solved

I think the most important single thing that you have to decide here today is how we can do this, how we can find a way in this very critical time of war when all the young men are needed for combat service, to get the proper type of young man to come from the services, for that is where they must come from, in the main, and enter our medical schools—the right kind of material so that we have the proper kind of doctors in the years coming along.

I am not going to say any more than just that at this time. There will be a great deal said by men who have a very broad knowledge of this whole subject. I expect to do all that I can to help.

I have to go over now and talk to the ladies, your wives, and I am just thinking what I may say to them. Well, I can, fortunately, talk about much more pleasant subjects than this subject of how to get medical students. But, seriously, I hope that we shall come up with something constructive on this. Let's see if we can't find a way to make the people of this country realize that the health of this nation following this war is going to be one of the most important things that we shall have to look after for some time.

Introduction and Address of Dr. T. C. Routley of Canada

The Speaker introduced Dr. T. C. Routley, Secretary of the Canadian Medical Association, who addressed the House as follows:

Mr. Speaker and Members of the House of Delegates of the American Medical Association: Once again it is my proud privilege to bring before you the greetings of the members of the medical profession of Canada. On another occasion I said to you that we have a law in Canada which says that if a highway has been kept open for twenty-one years unimpeded it then becomes an open highway for all time. I claim that privilege this morning. I have been coming to you for twenty-one years and you have never stopped me, you have received me with open arms, and it would seem to me that in the future, Mr. Chairman, I should never question, as I never have in the past, the cordiality of your welcome, the breadth of your friendship and the desire you have always shown in giving me any information I asked for and in sending back to your brother practitioners in Canada the expression of your good will.

This morning as we meet here the eyes of the world are focused on the United States, Great Britain and Canada, but that focusing point is not in the United States or in Great Britain or in Canada. That focusing point is on the narrow strip of land in Normandy. There, under the direction of your great General Eisenhower, Britishers, Canadians and citizens of this great United States have embarked on the greatest war, the greatest achievement in the history of the world. I am sure before this great Association adjourns you will join your voices with all the rest of the men of good will in offering prayers for the success of your boys and ours on that venture.

I should like to think, Mr. Chairman, that when this war is over there will be another great meeting of Americans, Britishers and Canadians when you come back to us to repay the visit to us that we have long looked for, when your Association and the British Medical Association and the Canadian Medical Association may meet together in Canada. We will promise you that when and if you come we will extend to you, or at least we shall try to extend to you, the same affectionate greeting that you have always extended to me and my confrères when we have come to you.

May I once again thank you for your reception and promise you that in the next twenty-one years I hope to come back and I am sure that I can look forward to the days which lie ahead between your country and mine, where good neighbors will become better neighbors, if that were possible.

The House recessed at 12:30 p. m. to reconvene at 2 p. m.

Tuesday Afternoon, June 13

The House reconvened and was called to order at 2:15 p. m. by the Speaker, Dr. H. H. Shoulders.

The Speaker announced that under the provisions of the rules adopted yesterday the House was to go into Executive Session at 2 p. m. today, and asked whom the House desired to have present at that session.

Dr. Charles E. Mongan, Massachusetts, presented a list of those who should be permitted to be present at the Executive Session which as amended reads as follows:

Resolved, That the courtesies of the House of Delegates of the American Medical Association in executive session assembled be extended to the presidents of the several constituent state and territorial medical associations, to presidents, attorneys and active and executive secretaries of the constituent state medical associations and component county medical societies, to the editors of state journals, to the secretary of the Southern Medical Association, to the secretary of the Canadian Medical Association and to any Fellow of the American Medical Association present who has been certified as a Fellow in good standing and who has been vouched for by a member of the House of Delegates.

The amended resolution was adopted on motion of Dr. Mongan, seconded by Dr. E. G. Wood, Tennessee, and carried.

Executive Session

The Sergeants-at-Arms polled the House, after which the House went into Executive Session at 2:25 p. m., on motion of Dr. R. W. Fouts, Vice Speaker, seconded and carried.

Report of Reference Committee on Executive Session

Dr. Louis A. Buie, Chairman, presented the following report:

1. Resolution from National Medical Association: A resolution was presented to the Board of Trustees by the National Medical Association and referred by the Board to the House of Delegates without recommendation, which reads as follows:

WHEREAS, The present emergency has necessitated the induction of a large number of physicians into the armed forces of the United States and the number of Negro physicians for the care of their population was already too few before our entrance into the war in those sections of the country where the majority of the Negro citizens reside, and

WHEREAS, An opportunity for the scientific advancement of the Negro physicians, particularly in the South, is urgently needed; and

WHEREAS, The Negro physicians in that section of the United States are at present, because of constitutional or other reasons, excluded from many of the constituent societies of the American Medical Association, and

WHEREAS, In the present emergency an opportunity should be given by the aforementioned constituent societies to such Negro physicians as are qualified and who are members of the National Medical Association, to join the American Medical Association, and

WHEREAS, Many of the constituent societies of the American Medical Association, both South and North, have shown an increasing sympathy and helpfulness in the elevation of the standard of medical practice among the Negro physicians by allowing them use of their libraries, attendance at their scientific meetings and exhibits and the opportunity of practicing in municipal hospitals, we, the Liaison Committee, duly accredited and representing the National Medical Association, hereby

Resolve, That an appeal be made through the Board of Trustees and the House of Delegates of the American Medical Association to its constituent societies to continue and enlarge the opportunities for the elevation of the standard of medical practice among our Negro physicians by (1) Increasing municipal, county and state hospital facilities in which the Negro physician may practice, (2) allowing the members in good standing of the National Medical Association to become members of the constituent societies of the American Medical Association to the end that members of the National Medical Association, both South and North, may become members of the American Medical Association and thus enjoy the opportunities of the scientific features of the conventions

and partake more fully of the benefits of organized medicine; (3) until such changes as are necessary in the constitutions of the constituent societies of the American Medical Association can be brought about in those constituent societies which now exercise a bar to the membership of Negro physicians, that members of the National Medical Association be allowed the privilege of Associate Membership in the American Medical Association.

Respectfully submitted,

LIAISON COMMITTEE, NATIONAL MEDICAL ASSOCIATION.

DR. CLARENCE H. PAYNE, Chairman

DR. T. M. SMITH, President.

National Medical Association.

DR. JOHN T. GIVENS, Secretary.

National Medical Association.

Your reference committee has studied the resolution of the National Medical Association with interest and sympathy. It feels that the Negro physicians of this country should be offered every possible opportunity to improve their medical qualifications. It would urge component societies to extend all aid that is practical to the Negro physicians in their communities to the end that the quality of service rendered by them to their people may be steadily improved. It is recognized, however, that the decision as to membership in the component county medical societies or on hospital staffs is outside the jurisdiction of the American Medical Association and is a matter of local concern.

2. Resolutions on Council on Medical Service and Public Relations: Your reference committee has considered the Resolutions on Council on Medical Service and Public Relations introduced by Dr. J. R. Miller, Connecticut, which read as follows:

WHEREAS, The Council on Medical Service and Public Relations that was authorized by this House of Delegates at its annual meeting in 1943 has been created and is engaged on the program prescribed by the House of Delegates, be it now

Resolved, That this House approve and commend the activities and program of the Council on Medical Service and Public Relations as outlined in its several reports; and be it

Resolved, That this House urge the Board of Trustees of the Association to give ample financial support to the Council on Medical Service and Public Relations in order that its services may be extended and become more useful to the profession of medicine; and be it further

Resolved, That the Council on Medical Service and Public Relations be empowered to administer and direct the public relations activities of the American Medical Association that have to do with medical service and legislation.

Your reference committee has considered the resolutions of Dr. Miller of Connecticut and recommends the approval of the first and second portions of the resolutions and offers the following as a substitute for the third portion of the resolutions:

Resolved, That the Board of Trustees be urged to give early consideration to defining the status of the Council on Medical Service and Public Relations.

3. Resolutions on Secretary and on Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION: Your reference committee has given careful consideration to the resolutions from the California Medical Association dealing with the work of the Board of Trustees and the officers of the Association, which read as follows.

RESOLUTION ON SECRETARY OF THE AMERICAN MEDICAL ASSOCIATION

Resolved, That the Secretary of the American Medical Association be commended for his long, faithful and valuable service to American medicine and be assured of our affection and that the Board of Trustees be memorialized to appoint him as Secretary Emeritus for life on the expiration of his present term of office.

RESOLUTION ON EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

WHEREAS, The medical profession in America finds itself facing the most critical period of its existence, and

WHEREAS, Because of lack of understanding of basic issues and problems by certain officers of the American Medical Association, public opinion is turning against organized medicine, and

WHEREAS, These changes of public opinion allow various and certain pressure groups to advance their own selfish causes; and

WHEREAS, The political adherents of socialized medicine have seized on the rising tide of public criticism against organized medicine in an effort to accomplish their own desires, and

WHEREAS, The unnecessary continuous defensive attitude of some of the officers of the American Medical Association makes it impossible for them to take leadership in bringing about proper general understanding of the real public needs with respect to medical care and progress; be it

Resolved, That the House of Delegates of the American Medical Association requests the Board of Trustees to replace the present Editor of THE JOURNAL.

Never before has American medicine been so needful as now of unity. The desire to extend the high quality of medical service to all the people at a reasonable cost is the objective sought by all of us. Your committee is convinced that this can be attained more certainly if physicians throughout the nation would give their loyalty and support to those selected by this House of Delegates as members of the Board of Trustees and to the representatives selected by the Board itself.

Your committee commends the loyalty and the efficiency with which these officers have for many years served the Association in carrying out the policies established by the House of Delegates. Your committee would also commend the Board of Trustees of the Association for its judgment and wisdom in the management of the affairs of the Association.

Therefore the Reference Committee on Executive Session recommends that these resolutions be not approved.

4 Resolution on Washington Office: The following resolution was considered by your reference committee: Be it

"Resolved, By the house of delegates of the Idaho State Medical Association in session May 22, 1944, that we most heartily commend the action of the American Medical Association in opening an office in Washington, D. C., through which information relative to medical affairs may be freely furnished and legislative data relayed back to the profession, to the end that such reciprocal action may continue to support and enhance the high standard of medical care furnished to the American people. Therefore we petition the House of Delegates of the American Medical Association to take such action as may be necessary to limit the activities of the Editor to the editorship of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION."

This resolution, submitted by the Idaho delegate, was considered in conjunction with the California and Connecticut resolutions. In view of our recommendations on these two resolutions and the action of the House of Delegates, your reference committee recommends the rejection of this resolution.

5. Resolutions on Changing the Structure and Enlarging the Field of Activities of the American Medical Association: The following resolutions were referred to your reference committee:

The House of Delegates of the Michigan State Medical Society at its 1943 annual session instructed the Delegates from Michigan to the American Medical Association that they present the following resolutions:

WHEREAS, The American Medical Association in the United States is organized under charter provisions as laid down for organizing similar groups, and

WHEREAS, From the advice received it appears that under the purposes set forth in its Articles of Incorporation this organization is incorporated for the sole purpose of carrying on charitable, educational and scientific endeavor; and

WHEREAS, the advice received, at present, at least, is to the effect that the American Medical Association under its present charter has no right whatsoever to engage in economic or political activities but has only the right to engage in such activities as set forth above and as stated in the provisions of the laws under which this organization is incorporated, and

WHEREAS, The American Medical Association is at present exhibiting a most decidedly defeatist attitude because of these aforementioned provisions and is exhibiting this attitude principally expressed as because of fear of taxation and other fears, and

WHEREAS, The practitioners of medicine who support the American Medical Association desire that this medical organization in addition to the above set forth objectives, concern itself with economic and other aspects of medicine as well, and

WHEREAS, It would seem proper to change the complexion of the organizational setup for the association so that the American Medical Association might be eligible to engage in other than scientific, educational and charitable endeavor and if necessary to pay taxes, which might require the increasing of income or whatnot for this organization, and

WHEREAS, This suggested change should attain a free and untrammeled position for organized medicine in the political and economic structures of these United States of America so that the American Medical Association might assume its place as a force for the benefit of the practitioner of medicine as well as for the benefit of the patient served, realizing that good medicine depends, in part at least, on freedom from fear, which is one of the great freedoms recognized in the New Atlantic Charter, this present fear being fear of persecution and prosecution under the existing setup, be it therefore

Resolved, That the House of Delegates of the American Medical Association proceed to change and amend the organizational and incorporational setup of the American Medical Association so as to permit of economic and political activities being carried on by the American Medical Association; and be it further

Resolved, That the American Medical Association proceed to, if necessary, pay taxes, whatever may be assessed, and be it further

Resolved, That the Board of Trustees of the American Medical Association be requested to take appropriate steps to provide for necessary fiscal readjustment in the financial affairs of the American Medical Association so as to accommodate for such changes.

Your reference committee has given a great deal of consideration to these resolutions. It feels that the resolutions contain valuable suggestions but is not clear as to how these recommendations can be carried out from a practical standpoint. Therefore it recommends that these resolutions be returned to the Michigan State Medical Society for clarification and more specific recommendations.

The first section of the report of the reference committee, dealing with resolutions presented to the Board of Trustees by the National Medical Association, was adopted on motion of Dr. Buie, seconded by Dr. A. A. Walker, Alabama, and carried.

Dr. Buie moved approval of the second section of the report of the reference committee, approving the first two resolutions contained in the Resolutions on Council on Medical Service and Public Relations, and the motion was seconded by Dr. Thomas A. McGoldrick, New York, and carried.

It was moved by Dr. Buie, seconded by Dr. Lloyd Noland, Alabama, and carried, that the substitute offered by the reference committee for the third resolution contained in the Resolutions on Council on Medical Service and Public Relations be adopted.

Dr. Buie moved the adoption of the third section of the report of the reference committee, dealing with resolutions referring to the Secretary and to the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and the motion was seconded by Drs. A. A. Walker, Alabama, and G. Henry Mundt, Illinois. After discussion by Drs. Dwight H. Murray and E. Vincent Askey, California, and Dr. Buie, Dr. Buie moved that the third section of the report of the reference committee dealing with the resolution referring to the Secretary be adopted. This motion was seconded by Dr. G. Henry Mundt, Illinois, and carried.

It was moved by Dr. Buie, and seconded by Dr. G. Henry Mundt, Illinois, that the third section of the report of the reference committee dealing with the resolution referring to the Editor of THE JOURNAL, be adopted. There was discussion by Drs. Dwight L. Wilbur, California; A. A. Walker, Alabama; Henry A. Luce, Michigan; Allen H. Bunce, Georgia; Thomas S. Cullen, Maryland; William A. Mulhern, Georgia; G. Henry Mundt, Illinois, and Charles Gordon Heyd, Council on Medical Education and Hospitals, during which Dr. Morris Fishbein, Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was given the privilege of the floor on motion of Dr. A. A. Walker, Alabama, seconded by Dr. G. Henry Mundt, Illinois, and carried. A vote by ballot was requested by Dr. Henry A. Luce, Michigan, seconded by Dr. Walter B. Martin, Virginia, and, after discussion by Dr. E. H. Cary, Texas, tabled on motion of Dr. Cary, duly seconded and carried. Dr. Morris Fishbein, on request, addressed the House.

It was moved by Dr. Charles E. Mongan, Massachusetts, seconded by Dr. William A. Mulhern, Georgia, and carried, that there be a rising vote on the adoption of Dr. Buie's motion to approve the third section of the report of the reference committee, dealing with the resolution referring to the Editor of THE JOURNAL. The Secretary announced that the vote was 144 approving that part of the reference committee's report to 9 opposing it, and the Speaker declared that section of the report of the reference committee adopted.

On motion of Dr. Buie, seconded by Dr. Robert F. Schluter, Missouri, and carried, the fourth section of the report of the reference committee, rejecting the Resolution on Washington Office, was adopted.

Dr. Buie moved that the fifth section of the report of the reference committee, recommending that the Resolutions on Changing the Structure and Enlarging the Field of Activities of the American Medical Association be returned to the Michigan State Medical Society for clarification and for more specific recommendations, be adopted. The motion was seconded by Dr. Walter E. Vest, West Virginia, and carried.

On motion of Dr. Buie, seconded by Dr. Mather Pfeiffer, Illinois, and carried, the report of the reference committee was adopted as a whole.

Report of Reference Committee on Legislation and Public Relations

Dr. Thomas A. McGoldrick, Chairman, presented the following report:

Your reference committee has received several resolutions from this House which overlap or duplicate others. For that reason your reference committee has grouped many of these together, as our report will show, and their subjects have been covered in the general report on the Council on Medical Service and Public Relations. The resolutions were as follows:

1. Resolutions on Council on Medical Service and Public Relations: These resolutions have been referred also to the Reference Committee on Executive Session, which has reported its recommendation that the matter be referred to the Board of Trustees for action. Your reference committee concurs in that report.

2. Resolutions on Survey of Public Opinion: On these resolutions your reference committee expresses its approval of the value of such researches as requested by the California Medical Association. It recognizes too the value obtained by that association in a survey made by it of the state of California within the past year. There has been recently made a survey of the entire United States by the Opinion Research Corporation at the request of the National Physicians' Committee. This survey with all its findings and conclusions is at the service of the Council on Medical Service and Public Relations. If any additional surveys are deemed needed by that Council it may take steps to secure them. Your committee recommends that these resolutions be disapproved.

3. Resolution on Creation of Department of Public Health: The resolution that the House of Delegates of the American Medical Association request the Congress of the United States to create a Department of Public Health the head of which department shall be a cabinet officer, and to assign to such department all health activities of the federal government is similar to another resolution which has been approved in preceding years and is again offered for approval to the House.

4. Resolution on Political and Economic Interests of Physicians: The Resolution on Political and Economic Interests of Physicians and a similar resolution from the Silver Bow County (Montana) are covered in the report of the Council on Medical Service and Public Relations.

5. Resolution to Transfer the Emergency Maternal and Infant Care Program to Department of Public Health: Your reference committee recommends approval of this resolution.

6. Resolutions on Maternal and Infant Care to Wives and Infants of Enlisted Men: The resolution, introduced on the part of the Missouri State Medical Association, in reference to medical service to the wives and children of enlisted men in the four lower grades for the period of the war and referring particularly to the method of payment of services, is covered in the Report on the Council on Medical Service and Public Relations.

7. Resolution on Inauguration and Expansion of Voluntary Group Medical Service Plans: The resolution introduced by Dr. Luce of Michigan urges the American Medical Association to encourage the inauguration and expansion of voluntary group medical service plans. This resolution is covered in our report on the Council on Medical Service and Public Relations.

8. Resolution on United Public Health League: Your reference committee feels that, while the United Public Health League may represent the group included in its membership, it cannot adequately represent the remaining 115,000 members of the American Medical Association located in the other forty-two states. Your reference committee recommends that this resolution be not approved.

9. Report of Bureau of Medical Economics: During 1943 the Bureau of Medical Economics continued to stress the soundness of those principles adopted in 1934 and urged the medical profession to continue to be alert to deal with medical service plans. It has recognized the needs and value of prepayment plans in general and their necessary complexity. It

has studied compulsory sickness insurance of many countries. It has shown the necessity of standards of medical service. It has referred to the present operation of the prepayment plans in fourteen states of the Union. "The war emergency has brought definite governmental control of education and medical practice and has reduced to an almost dangerous degree the number of physicians serving the civilian population." Your reference committee recognizes the difficulties under which the bureau has worked with decrease of personnel and increased difficulties of obtaining exact information at this time. It recommends approval of this bureau's report.

10. Report of Bureau of Public Relations: Your reference committee notes with interest and approval the many activities that the Bureau of Public Relations and the valuable and successful efforts it has made to furnish accurate information to newspapers, periodicals and news agencies and other mediums of public information. "It has collaborated in the public relations of many national organizations and has aided the war effort by disseminating material from governmental agencies to both the medical profession and the public." It has called special attention to the survey made by the Opinion Research Corporation at the request of the National Physicians' Committee and stressed many valuable deductions from that survey. Your reference committee recommends approval of this report.

11. Report of Bureau of Legal Medicine and Legislation: (a) Licensure: Your reference committee approves the suggestions made in regard to medical licensure with the additional statement that regulations for licensure be left to the individual licensing boards. (b) Demerol: Your reference committee recommends that this drug be placed under the same regulations as narcotics. (c) Obstetrics: While your reference committee approves the general program of care for wives and infants of servicemen, it disapproves the methods of payment. It is convinced that the full control and regulation of this program should be placed completely in the public health department of each state.

Your reference committee commends the action of the Bureau of Legal Medicine and Legislation on its work in keeping physicians informed of laws enacted and legislation pending and in particular on its studies of the activities of the sponsors of the Wagner-Murray-Dingell bill. It recommends the approval of the report.

12. Report of Council on Medical Service and Public Relations: Your reference committee refers to the report of the Council on Medical Service and Public Relations. This report for the past year shows a tremendous amount of work and much accomplishment. The Council has collaborated with the Bureau of Medical Economics, the Bureau of Legal Medicine and Legislation and the Bureau of Public Relations. It has published its studies of pending legislation, especially on the Wagner-Murray-Dingell bill. It has sent semimonthly bulletins of its activities to all component societies and constituent associations, to all state association secretaries and other officers, to members of the House of Delegates and to others to a number exceeding 2,000 names.

"Considerable study has been given to the subject of voluntary insurance diagnostic clinics and medical service bureaus." "It has established an office in Washington, D. C., for the collection of information and data concerning medical care and its distribution, its availability, its costs and its control in various parts of the United States. The information thus collected to be made available to the medical profession and to other appropriate agencies interested in the extension of medical service and the provision of medical care and related subjects."

Your reference committee approves the recommendation that the Board of Trustees prepare a plan whereby students of approved medical schools may become student members of the American Medical Association.

Your reference committee asks the House of Delegates to instruct the Council on Medical Education and Hospitals to take necessary steps to have each approved medical school give an adequate course in medical sociology, medical economics and medical ethics.

The unionization of employees in hospitals might jeopardize the health, safety and lives of patients. Your reference com-

mittee urges strongly the opposition of the House of Delegates to such activities.

Your reference committee recommends approval of the bill introduced by Congressman A. L. Miller of Nebraska which would transfer all government agencies dealing with health to the United States Public Health Service. This recommendation is in harmony with the recommendation previously made that the administration and control of emergency maternity infant care programs be placed in the public health departments of the individual states.

Your reference committee recommends that the House of Delegates do not authorize the reorganization or the amalgamation of the Bureau of Medical Economics with the Council on Medical Service and Public Relations.

Your reference committee feels that the recommendation of the Council be approved and that it be authorized to employ a director of medical prepayment insurance with necessary assistants when and where they may become essential.

Your reference committee reiterates approval of the platform of the American Medical Association adopted by the House six years ago and embodied in the supplementary report of this Council. There is no change in the platform itself. The added explanatory changes offered by the Council elucidate and merit approval. Your reference committee recommends approval of this report.

13. Resolutions on Tuberculosis Control: Your reference committee is in full sympathy with the purposes of the act and the objection of the proposers. It fully recognizes the gravity of the disease and the danger that follows its lack of control. In this proposed act, vast power is given to the central government through the Surgeon General of the United States Public Health Service subordinate in all financial matters to the Federal Security Administration. No money may be appropriated or expended for the purposes of this act without the approval of the Federal Security Administration. The initial appropriation asked for the first year is \$10,000,000, and for each year thereafter "a sum sufficient to carry out the purposes of this act." Furthermore, other ways may be provided for attaining the objective, as for example direct aid to needy communities in the Lanham act. Your reference committee recommends disapproval of the resolutions.

Section 1 in the report of the reference committee, concurring in the report of the Reference Committee on Executive Session adopted by the House, needed no action.

The second section of the report of the reference committee, disapproving of Resolutions on Survey of Public Opinion, was adopted on motion of Dr. McGoldrick, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried.

Dr. McGoldrick moved that section 3 in the report of the reference committee, approving the Resolution on Creation of a Department of Public Health, be adopted, and the motion was seconded by Dr. George W. Kosmak, New York, and carried.

The fourth section of the report of the reference committee, referring to Resolution on Political and Economic Interests of Physicians, is covered in the report of the reference committee on report of the Council on Medical Service and Public Relations.

On motion of Dr. McGoldrick, seconded by Dr. J. F. Hassig, Kansas, and carried, the fifth section of the report of the reference committee, approving the Resolution to Transfer the Emergency Maternal and Infant Care Program to Department of Public Health, was adopted.

The Resolutions on Maternal and Infant Care to Wives and Infants of Enlisted Men, referred to in the sixth section of the report of the reference committee and the Resolution on Inauguration and Expansion of Voluntary Group Medical Service Plans referred to in the seventh section of the report are covered in the report of the reference committee on the report of the Council on Medical Service and Public Relations.

Dr. McGoldrick moved that section 8 of the report of the reference committee, disapproving the Resolution on United Public Health League, be adopted, and the motion was seconded by Dr. Walter E. Vest, West Virginia, and carried, after discussion by Dr. Dwight H. Murray, California.

The report of the reference committee recommending approval of the report of the Bureau of Medical Economics, as contained in section 9, was approved on motion of Dr. McGoldrick, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried.

On motion of Dr. McGoldrick, seconded by Dr. Louis A. Van Kleeck, New York, and carried, section 10 of the report of the reference committee, recommending approval of the report of the Bureau of Public Relations, was adopted.

Dr. McGoldrick moved, and the motion was seconded by Dr. Francis F. Borzell, Pennsylvania, and carried, that section 11 of the report of the reference committee, approving the report of the Bureau of Legal Medicine and Legislation, be adopted.

It was moved by Dr. McGoldrick, and duly seconded, that the twelfth section of the report of the reference committee, dealing with the report of the Council on Medical Service and Public Relations, be adopted. Dr. Louis H. Bauer, New York, remarked that the statement was not quite accurate, as eight supporting items are from the old platform, but the item adopted as a platform is entirely new, namely that the first item is the platform. Dr. McGoldrick stated that with this correction your reference committee recommends the adoption of that platform as embodied in the supplementary report of the Council on Medical Service and Public Relations. The motion to adopt the report as amended was then seconded by Dr. Louis H. Bauer, New York, and carried.

The report of the reference committee contained in section 13, disapproving of Resolutions on Tuberculosis Control, was adopted on motion of Dr. McGoldrick, seconded by Dr. Robert H. Hayes, Illinois, and carried after discussion by Dr. McGoldrick; Dr. Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health; Dr. Thomas S. Cullen, Maryland, and Dr. Francis F. Borzell, Pennsylvania.

On motion of Dr. McGoldrick, seconded by Dr. J. F. Hassig, Kansas, and carried, the report of the reference committee was adopted as a whole, after discussion by Drs. Lee O. Frecht, Illinois, and Louis H. Bauer, New York.

Presentation and Address of Lieutenant General Robert Kho-sheng Lim

Major General George F. Lull, United States Army, presented Lieutenant General Robert Kho-sheng Lim, Director of Planning of the Medical Department of the Chinese Army, who addressed the House as follows:

Mr. Speaker, Colleagues of the American Medical Association: I feel it is a very great honor to have been asked to come to attend your meeting here today. I feel it an honor because over in China, where we have so few doctors trained in modern medicine, the large majority have been trained in American medical schools. In China today the difficulty that we are facing is largely a lack of trained personnel. We have 2,000 doctors to look after 8,000,000 men. You will no doubt wonder how any medical service can be given, but fortunately we can to some extent apply the principles of scientific medicine or, better, scientific health, and by putting forward many of the principles and methods that you have taken in this country for your own purposes during the war (I refer to the policy of putting prevention of disease foremost) I believe that we have been able to sustain the health of our armies to a degree that is really surprising. I won't take up your time. I want again to thank you for your kindness and the privilege of being able to attend the meeting and to speak here.

On behalf of the House the Speaker expressed to General Lim the appreciation of the House for his presence.

Resolution Requesting Dr. Roger I. Lee to Resign as Trustee Immediately, Thereby Removing Constitutional Bars to His Eligibility as Candidate for President-Elect

Dr. Floyd S. Winslow, New York, presented the following resolution, which the House, sitting as a Committee of the Whole, on motion of Dr. Winslow, seconded by Dr. George W. Kosmak, New York, and carried, considered:

WHEREAS, This is a critical period in American medicine; and
WHEREAS, Able, constructive leadership has never been more necessary, than at the present time; and

WHEREAS, The present chairman of the Board of Trustees, with ten years' experience on the Board, is better qualified than any one else to assume the leadership of the American Medical Association; and

WHEREAS, The provisions of the Constitution and By-Laws of the Association render any general officer of the Association ineligible for election as President-Elect; and

WHEREAS, The term of office of the present Chairman of the Board of Trustees expires at the close of the present session, and having served two terms he is ineligible for reelection as Trustee and, therefore, his ineligibility is a technicality of a few hours, therefore be it

Resolved, By the House of Delegates of the American Medical Association that it calls on Dr. Roger I. Lee, Chairman of the Board of Trustees of the American Medical Association, to resign his office as Trustee immediately, thereby removing all constitutional bars to his eligibility as a candidate for the office of President-Elect.

With Dr. Winslow presiding over the House as a Committee of the Whole, the resolution was adopted by the Committee of the Whole, on motion of Dr. James Q. Graves, Louisiana, seconded by Dr. George W. Kosmak, New York, and carried.

On motion of Dr. Louis H. Bauer, New York, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the Committee of the Whole rose to report to the House.

The Speaker resumed the Chair and Dr. Winslow reported that the Committee of the Whole recommended adoption of the resolution referring to Dr. Roger I. Lee. On motion of Dr. George W. Kosmak, New York, seconded by Dr. Thomas A. Pitts, South Carolina, and carried, the recommendation of the Committee of the Whole was adopted.

Tuesday Afternoon—Continued

On motion of Dr. R. W. Fouts, Vice Chairman, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, the House went into regular session at 4:20 p. m., with the Speaker, Dr. H. H. Shoulders, presiding.

Resolution on Neuropsychiatric Casualties

Dr. H. A. Luce, Michigan, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, President-Elect Herman L. Kiet-chner gave special attention in his address to the neuropsychiatric casualties of our country which have developed as a result of the war, and

WHEREAS, In his wisdom and judgment he indicated that the House of Delegates of the American Medical Association should take some action toward the treatment and consideration of neuropsychiatric disabilities; be it

Resolved, That the House of Delegates request the President of the American Medical Association for the year 1944-1945 to appoint a committee and take such steps as in his judgment may seem to be indicated in the consideration of the above referred to problems.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. E. S. Hamilton, Chairman, presented the following report:

1. Conference with Board of Trustees of American Optometric Association: Your reference committee has reviewed the report of the conference with the Board of Trustees of the American Optometric Association, and carefully read their statement presented in the Handbook. The attention of the House of Delegates is especially directed to article 4 of their statement, as follows: "4. Mutual professional respect and support; the broadening of the bases of contact and scope to the end that all practitioners who are concerned with matters of eyes and eyesight and the problems of vision from any corrective or alleviative standpoint may be included in and of necessity become integral parts of such a cooperative association of mutually interested and allied professions and health services."

In view of the action of the House of Delegates in 1935, when consultation between oculists and optometrists was disapproved, said action being affirmed in 1936 and 1940, your reference committee recommends that the request of the American Optometric Association for conference with the representatives of the American Medical Association be denied.

2. Legislative Recognition of Cultists: Your reference committee has thoroughly reviewed the report as printed in the Handbook. It is heartily in accord with the statement of the Council on Medical Education and Hospitals that "only graduates of approved schools of medicine should be licensed in the practice of medicine."

Your reference committee approves the entire report and recommends its adoption by the House of Delegates.

Respectfully submitted,

EDWIN S. HAMILTON, Chairman.
OLIN H. WEAVER.
J. B. LUKINS.
ROBERT E. SCHLUETER.
FRANCIS J. SAVAGE.

It was moved by Dr. Hamilton, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried after discussion by Dr. Walter B. Martin, Virginia, and Dr. Bedell, that the first section of the report of the reference committee, dealing with Conference with the Board of Trustees of American Optometric Association, be adopted.

Dr. Hamilton moved the adoption of section 2 of the report of the reference committee, approving the report of the Board of Trustees on Legislative Recognition of Cultists as printed in the Handbook. The motion was seconded by Dr. Mather Pfeiffer, Illinois, and carried.

On motion of Dr. Hamilton, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the report of the reference committee was adopted as a whole.

Report of Reference Committee on Miscellaneous Business

Dr. H. A. Luce, Chairman, presented the following report, which on motions of Dr. Luce, duly seconded and carried, was adopted section by section and as a whole:

1. Rereferred Resolution on Dr. Horace Wells of Hartford, Conn.: This resolution has been considered by your reference committee, which is aware of the controversial nature of priority claims regarding the initial application of anesthetic agents.

Your reference committee wishes to give honor to whom honor is due and to deny to no one seniority rights and recommends the substitution of the following resolution for the one introduced by Dr. Miller.

"WHEREAS, 1944 marks the centenary of the application of a practical method of anesthesia by nitrous oxide by Dr. Horace Wells of Hartford, Conn.; therefore be it

Resolved, That the House of Delegates of the American Medical Association commends and endorses the celebration during 1944 of the centenary of this application of nitrous oxide anesthesia by Dr. Horace Wells of Hartford, Conn."

2. Resolution on Simplification and Standardization of Insurance Forms: Your committee approves the resolution as introduced with the following changes: substitution of the word "requested" for the word "instructed" in the last paragraph and the changing of the latter part of the paragraph beginning "with a view" to read "with a view toward developing simplification and standardization of forms" so that the resolution as approved by your reference committee reads: "*Resolved*, That the Board of Trustees of the American Medical Association shall be requested to arrange for a series of conferences between representatives of the American Medical Association and representatives of private insurance carriers with a view toward developing simplification and standardization of forms."

Respectfully submitted,

HENRY A. LUCE, Chairman.
CHARLES G. STRICKLAND.
LUCIUS F. DONOHUE.
ROBERT A. PEERS.
ROBERT H. HAYES.

Resignation of Dr. Roger I. Lee as Trustee

The Speaker called on Dr. Roger I. Lee, Chairman Board of Trustees, who addressed the House as follows:

Mr. Speaker, Members of the House: As a Delegate for a number of years and as a Trustee for ten years, I have always with the greatest humility bowed to the action of the House of Delegates. I hereby bow once more to the action of the House of Delegates and I resign as Trustee.

On motion of Dr. George W. Kosmak, New York, seconded by Dr. Floyd S. Winslow, New York, and carried, the resignation of Dr. Roger I. Lee as Trustee was accepted.

On motion of Dr. T. K. Gruber, Michigan, duly seconded and carried, the House recessed at 4:40 p. m. to convene at 12 noon on Thursday, June 15.

Third Meeting—Thursday Afternoon, June 15

The House of Delegates was called to order at 12:10 p. m. by the Speaker, Dr. H. H. Shoulders.

The Speaker called on a veteran member of the House, Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, who delivered a prayer as follows:

Oh, Lord God of Hosts, Who has safely brought us to the beginning of this day, we beseech Thee to look down on these, Thy servants, especially those in the armed forces who are fighting for the restoration of peace. Theirs is a mighty battle. Give them courage, guide the sick and wounded to a happy issue out of all their afflictions that they may live on to fight for the Cross of Jesus. We pray, oh Lord, that the captives and the suffering ones may be restored to normal life and happiness. We pray for all sorts and conditions of men who need strength and greater faith in Thee.

May this great country of ours maintain freedom and liberty and righteousness of life. May medical science and art forever have the background of humanity. Bless, oh Lord, our loved ones in special danger and return them to their homes in Thy love and service.

Again we commend to Thy care those who are in sorrow, sickness or adversity. We pray for the peace that passeth all understanding. May faith abide with us and right be our guiding star.

We open this meeting with the belief that God will lead us on to a better life for all humanity. It is promised that when two or three are gathered together in Thy name Thou wilt grant their requests. God hear us and have mercy on us. Christ hear us and have mercy on us in this raging conflict. Preserve us in body and soul, through Jesus Christ our Lord, to whom with Thee and the Holy Ghost be all honor and glory. Amen.

Presentation and Address of Major General David N. W. Grant

On request of the Speaker, Dr. Frank H. Lahey, Past President, presented to the House Major Gen. David N. W. Grant, Air Surgeon, Army Air Forces, who addressed the House as follows:

Dr. Paullin, Dr. Kretschmer, Mr. Chairman and Members of the House of Delegates: It was my pleasure and my privilege last year on a similar occasion and my duty to report to you what we in the Army Air Forces are trying to do with our medical officers. I reported to you last year that we were endeavoring by every means possible to use the proper man in the proper place and to economize on doctors within the limits of the necessity. At that time I reported that some 97 per cent of the specialists were promptly assigned to the Air Forces, and I am happy to report that this figure remains approximately the same and that the same interest is being carried on within the medical services of the Army Air Forces to continue the proper assignment.

Many problems have appeared in the last year. Now that we are dealing with war casualties there is one which is of very vital concern. Personally I am disturbed, very much disturbed, over what to me is a great deal of loose talk over the so-called psychoneurotic. As you probably know, the Army Air Forces have been pioneering in convalescent and rehabilitation work for the past eighteen months and we have got eighteen months' experience behind us. Our records show that we are returning to duty approximately 85 per cent of our people, be they war casualties or the so-called psychoneurotic. We are vitally concerned with this so-called flying fatigue, call it what you may—some speak of it as a psychoneurosis in relation to flying.

Of the combat people returned from the theaters with pronounced operational fatigue, 68 per cent have been put in condition to return to combat duty (I don't think you would call that psychoneurotic) and 85 per cent of all of them are returned to flying duty.

I don't think we have any right to label these boys psychoneurotic when they are normal individuals, the same as we are, who have been put under tremendous stress, and they need rest and, you might say, medical guidance. We in the Air Forces

are greatly disturbed over the trend of loose publicity with relation to the term "psychoneurosis."

This brings us to the point of postwar planning. You have no doubt seen in the papers General Arnold's announced policy in reference to the men in the Air Forces, that he is endeavoring to return them to civil life in as good condition as when they came, or in better condition, as far as possible. That covers the people in the Army Air Forces; it covers all branches of people in the Army Air Forces.

It naturally follows that you will want the question answered: What about these doctors in the Army Air Forces? What is your postwar plan? I can tell you that for two years the office of the Air Surgeon has been working on and revising postwar plans in reference to the doctors who are serving with the Army Air Forces, that these plans call for training or postgraduate study for any medical officer who so desires such training on his separation from the service. I stated here last year, and we still have that policy, that our one aim is to return these doctors to civil life at least as good doctors and, we hope, better doctors.

I am not prepared at this time to tell you how this will be done, whether in civilian institutions or Army institutions, because from the civilian institution standpoint legislation will have to be passed. I can only say that it is written into the broad plan of the Army Air Forces today, which covers the medical people serving with the Army Air Forces.

For your information, to show you what we are trying to accomplish in this, I might mention to you that during the last year we have given a few over 500 young men six months' recognized resident training, and 30 per cent of that number we have continued on to a full year of recognized resident training.

I need only add that it is the policy of the Army Air Forces that this training continue and that we are continuing it at this time, and certainly as long as I am in office it will be continued.

Presentation and Address of Major General Norman T. Kirk

On request of the Speaker, Dr. Fred Rankin, Past President, presented to the House Major General Norman T. Kirk, Surgeon General of the United States Army, who addressed the House as follows:

Thank you very much. It is a pleasure and an honor again to address the Delegates of the American Medical Association. I was told three minutes ago that I was going to do this.

Maybe we had better go into the organization of the Medical Department of our Army. Before the Army was reorganized, just prior to the war, there was the Surgeon General of the Army on the staff of the Chief of Staff. Then the Army was reorganized into the Ground Forces, the Air Forces and the Service Forces. The Surgeon General of the Army became the Surgeon General of the Army Service Forces, with General Grant appointed as Air Surgeon of the Air Forces, and another medical officer, who was initially General Bessé, who has served two years in the North African campaign, now serving with the Ground Forces. So the Medical Department has been split more or less three ways at home.

Overseas, the medical installations in each theater operate under a surgeon in that theater who is on the staff of the commanding general of that theater. The medical department procured early on their own, later through Assignment and Procurement, medical officers and nurses for the armed forces. The air forces in this general procurement program procured medical officers for those forces. All medical supplies that have been purchased—and it has been a big job—for the armed forces have been purchased out of the Office of the Surgeon General and distributed under the direction of the officer or civilian in charge of medical supplies, and we have been classified in many departments as the supply branch. That is only a small part of our job, yet General Somervell recently, on a trip around the world, came back and said that the best supply job done in all the theaters was done by the medical department. That is a lot from General Somervell. He is a fine boss, he is a great soldier; he calls a spade a spade. If one isn't pro-

ducing, one is in trouble. We were in trouble early in the supply game. Manufacturers didn't produce things that the medical department needed. They didn't make instruments; they all came from Germany. Many other things were required in this great expansion of ours that were not available, were not manufactured, so I can tell you today that the medical department is leading not only overseas but at home in the supply game.

Hospitalization: General Grant and I had an opportunity to visit England in March. General Hawley has been surgeon of that theater; he has been over there some two years, has planned and built it and has done a splendid job. There have been wonderful hospitals constructed, some turned over to us by the British, others built of brick, of hollow tile or huts that are well sealed, and the hospitals are there, with many beds, thousands of beds—I can't tell you how many—to be ready for D-Day, which has already happened. There are abundant medical supplies over there, and the personnel staffing those station and general hospitals are doing a grand job. I wish you could see them. You would be proud of them, particularly these affiliated units that have been working for the past two years.

Hawley has cheated a bit on his policy of evacuation back home. He has kept those patients over there so that those people would have something to do in those grand units. We have some femurs over there being returned to duty in the theater, and we all know it takes six to eight months to get a compound femur back to duty. He set up over in that theater and took leadership, and it is better than we have.

I can't agree with General Grant that psychoneurosis isn't a problem in the Army and shouldn't be talked about. I can't state statistics, I am not permitted, but they have been stated as to the number of men that have been discharged from the Navy, from the Army, from the Air Forces, because of psychoneurosis. Over there we saw something that was being done to train medical officers to take care of battle fatigue, whether it was the normal or the psychoneurotic that got that far, and it is a wonderful job, better than we are doing at home. We saw men in there being given barbiturates, put to bed, fed, who were 15 or 20 pounds underweight and were gaining a pound a day under that treatment, and they were reconditioned. In that theater there has been set up a better reconditioning unit than anywhere at home or abroad. A grand job is being done over there.

We visited the Eighth Air Force that had been bombing Germany. General Grant and I had an opportunity to be there when a flight returned to one of those bases on the third day over Berlin and to see what casualties came back. We wanted to see how it happened at the front. It so happened that every plane came back. The only casualty was a man with a piece of flak that had gone through the back of his hand and had taken a bit of skin off his hand.

In all those airfields there were set up excellent dispensaries to give first aid to the casualties that flew back in those bombers. Then they were evacuated to the station hospitals set up by the ASF under Hawley, where there were wards set up to treat shock day or night when these casualties came back. We saw some of those casualties that happened the night before. We saw one man who had lost a kidney. The laminae had been taken off of three lumbar vertebrae. The General over there who heads up the surgery of that air force has done a grand job in building armor to protect these men from low velocity missiles; it buttons up the side, but this missile went through. It required the removal of this man's kidney. The spinal cord was temporarily out. The fellow was doing excellently. We saw many other battle casualties that were excellently handled there. They stayed in those station hospitals that were set up in that Eighth Air Force and then were transferred to the general hospital. They were doing a grand job.

All hospitalization overseas is done by ASF. They are brought home in two ways. Over there the air service has done a grand job in evacuating casualties from the theater; they have evacuated more than 180,000 casualties, and I don't believe that the campaign could have gone on if it hadn't

been for evacuation of wounded from the front back to our bases. It is a hundred mile haul by ambulance and then they are put in airplanes and brought up. There is a three hour haul then by air to our bases. There wouldn't have been railroads or hospital trains to get those patients back. That is the story in that theater, and that is the story in the Southwest Pacific. A grand job has been done in evacuation by air of our battle casualties.

They come home from these general hospitals that I have told you about by hospital ship or troop ship and by air. These grand four motored airplanes that are now available, I am informed by General Grant's office, are more and more bringing back battle casualties and sick from overseas. When they come back, all battle casualties are received in our general hospitals, ASF general hospitals, for definitive care for their war wounds. A grand job is being done in those hospitals here at home. I have visited a lot of them, and so have many of you.

There are sixty of those hospitals with more than a hundred thousand beds that have been set up and are ready to take care of what comes from this push across the Channel. Plans have been made to take care of convalescents, to augment those beds if we need more, and for the reconditioning that is also going on in the Army service.

I think you might be interested in the setup of plans for D-Day when this push came across and we really started to fight this war. We have just started to fight this war. We are ready to pour men in there to win this war, and the medical department has a plan that is backing up those gallant troops that are going to make this drive to win the war.

When those units went over they attached medical companies. Two medical aid men went forward with each company that went into attack to supply first aid to the first men wounded. The litter bearers came forward to carry those men back to the aid stations that were set up on the beachhead when the battalion first landed. Then they were put on certain selected LST boats that brought over tanks and infantry and whatnot, manned by Navy personnel, Navy medical officers and Corps men who gave first aid in these LSTs, which before they left the home shore were supplied with the necessary medical equipment for dressing stations and operating rooms aboard the hospital ships that carried these battle casualties and battle sick back to the home shore, where there were ambulances and hospital trains available to take them to hospitals.

As those troops advanced, the medical battalion came in with its collecting stations and clearing stations, and those clearing stations were supplemented by surgical teams to take care of the nontransportable patients. As they advanced and a division came ashore, platoons of field hospitals and evacuation hospitals landed on the beach head to give primary surgery on the beach head rather than transport them back by boat to England for primary surgery. And so the plan is in operation as it has been studied and developed to take care of the battle casualties that ensue from this invasion.

There are general hospitals there in England that will go forward and set up in France. These units have been there operating for a year, two years, and then have been pulled out, ready to go up with their equipment to set up general hospitals in France, while newer units come over and take over the job they were doing in England. That is the plan of medical service in that theater.

I want to thank the American Medical Association for the help that it has given the Surgeon General's Office in selecting specialists and making available this information about doctors as to what they can do and not what they think they can do. With the help in our office of such men as General Rankin and Hugh Morgan and others from you who have come in to assist us, those men have been placed on the jobs where they are doing excellent work. With 40,000 men in the Medical Department and with excellent care that we are seeing that the sick and wounded are receiving, it isn't by chance that this all happened. It was planned, and the right man was put in the right job to do that job.

I thank you for allowing me to talk to you. I am afraid I have talked too long.

Report of Reference Committee on Credentials

Dr. Dearing G. Smith, Chairman, reported that there are 170 Delegates registered out of a possible total of 175, which your reference committee believes is a wonderful record in these troublous times.

Roll Call

The Secretary called the roll and announced that more than a quorum had responded.

Presentation of Minutes

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Thomas A. McGoldrick, New York, and carried, the House dispensed with the reading of the minutes.

Report of Reference Committee on Medical Education

Dr. Charles H. Phifer, Acting Chairman, presented the following report, which on motions of Dr. Phifer, duly seconded and carried, was adopted section by section and as a whole:

1. Resolution Requesting Board of Trustees to Prepare a Concise Statement of Achievements of the Medical Profession for Submission to Boards of Education Your reference committee is in accord with the recommendation of the Board of Trustees that the Resolution Requesting the Board of Trustees to Prepare a Concise Statement of Achievements of the Medical Profession for Submission to Boards of Education be not approved, since the intent of the resolution has been accomplished through publication of material on the achievements of medicine in practically every issue of *HYGIEA* and also through the several histories of medicine which have been published recently.

2. Resolution on Lifting of Sex Discrimination from Young Women Desiring to Study Medicine: Your reference committee recommends that this resolution be not approved. It is the belief of the reference committee that there is no large reservoir of qualified premedical women from which schools could select substantially increased numbers of women medical students. With regard to alleviating or aiding the financial status of women and other civilian medical students, the deans of medical schools are acquainted with various loan and scholarship funds. This information should be made available to civilian students. Your reference committee recommends that this resolution be referred to the Council on Medical Education and Hospitals with instructions that it give every consideration to the problem.

Respectfully submitted,

WILBURT C. DAVISON, Chairman.
THOMAS S. CULLEN.
CHARLES H. PHIFER.
FRANCIS F. BORZELL.

Report of Reference Committee on Legislation and Public Relations

Dr. Thomas A. McGoldrick, Chairman, presented the following report, which was adopted section by section and as a whole, on motions of Dr. McGoldrick, duly seconded and carried:

1. Resolution on Neuropsychiatric Casualties: Your reference committee recommends that the resolution introduced to carry out the suggestions of President-Elect Herman L. Kretschmer that the President of the American Medical Association for the year 1944-1945 appoint a committee to take such steps as may seem to be indicated in the consideration of the subject of neuropsychiatric casualties due to war be adopted.

2. Resolution on Consolidation of Federal Health Activities in a Single Federal Department: Your reference committee feels that the work described in H. R. 4371 could best be done through the state and local authorities with monies allotted to them by the Secretary of Labor rather than through the United States Public Health Service as suggested in this resolution. Your reference committee recommends disapproval of the resolution.

3. Resolutions on American Medical Association Legislative and Public Relations Activities: The matter introduced by Dr. Dillinger of Indiana, on behalf of the Indiana State Medical Association, concerning the organization of an office for the Council on Medical Service and Public Relations in Washington, D. C., has been covered in our report on this Council and needs no further action.

Respectfully submitted,

THOMAS A. MCGOLDRICK, Chairman.
FLOYD NOLAND.
H. G. HAMER.
WILLIAM R. MOLONY SR.
ROBERT L. ANDERSON.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. E. S. Hamilton, Chairman, presented the following report, which on motion of Dr. Hamilton, seconded by Dr. William A. Mulherin, Georgia, and carried, was adopted:

Resolutions on Speakers' Bureau: Your reference committee is wholly in accord with these resolutions and recommends that they be approved.

Respectfully submitted,

EDWIN S. HAMILTON, Chairman.
OLIN H. WEAVER.
J. B. LUKINS.
ROBERT E. SCHLUETER.
FRANCIS J. SAVAGE.

Resolutions on Compensation for Full Time Health Officers from the Section on Preventive and Industrial Medicine and Public Health

Dr. Arthur J. Bedell, Section on Ophthalmology, in behalf of Dr. Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health, who was called home on yesterday, presented the following resolutions from the Section on Preventive and Industrial Medicine and Public Health, which, on motions of Dr. G. Henry Mundt, Illinois, seconded by Dr. George W. Kosmak, New York, and carried, were referred to the Board of Trustees:

WHEREAS, The practice and administration of public health has become a specialty within the practice of medicine for which more and more physicians are specially trained and in which they pursue lifetime careers; and

WHEREAS, The safeguarding and the improvement of the health of the people have always been a primary concern of the medical profession, and our responsibility in this field is so important that it has attracted and should continue to attract some of the ablest members of our profession; and

WHEREAS, Health officers have often devoted their lives to this field at the cost of considerable personal sacrifice, such as inadequate compensation, political interference, insecure tenure of office, lack of facilities for research or opportunities for personal advancement; and

WHEREAS, The American Medical Association has pointed out the fact that many sections of the country are without the benefits of full time trained health officers and that there is great need for more well trained physicians in this field; now therefore be it

Resolved, That it is the considered opinion of this Association that the full time health officers and other full time medical specialties in the public health field who have been specially trained for their highly important work should be compensated for their services in a manner comparable with the net professional income of the good surgeons or internists of the community, and further

Resolved, That adequate compensation and reasonable security in tenure of office will be necessary before physicians with proper qualifications to assume the heavy responsibility of protecting and improving the health of the public will be available in sufficient number to meet the nation's existing needs

These resolutions were passed by the Section on Preventive and Industrial Medicine and Public Health on Wednesday morning, June 14, at the Stevens Hotel, Chicago.

Resolution on Formation of Anesthesia Study Commissions

Dr. Henry S. Ruth, Section on Anesthesiology, presented the following resolution adopted by that section, which was adopted on motion of Dr. Ruth, seconded by Dr. F. Leslie Sullivan, New York, and carried:

WHEREAS, There has been introduced a variety of anesthetic drugs and methods during recent years; and

WHEREAS, A more rapid and accurate method of evaluating these new anesthetic practices is desirable; and

WHEREAS, There is accumulating evidence that misinformation exists concerning safe administration of anesthetic drugs; and

WHEREAS, It has been demonstrated that anesthesia study commissions are of educational value to the medical profession; now therefore be it

Resolved, That the American Medical Association should encourage the formation of anesthesia study commissions within the state, county and other similar medical societies.

ELECTION OF OFFICERS

The Speaker declared the next order of business to be the election of officers.

Election of President-Elect

Dr. Walter G. Phippen, Massachusetts, nominated Dr. Roger I. Lee, Boston, for President-Elect, and the nomination was seconded by Drs. A. A. Walker, Lloyd Noland, Alabama; Thomas A. McGoldrick, New York; John H. O'Shea, Washington; Edward R. Cunniffe, New York, and William A. Mulherin, Georgia; the Michigan delegation; Drs. Edwin S. Hamilton, Illinois; H. B. Everett, Tennessee; Thomas A. Pitts, South Carolina; Robert A. Peers, California; James R. Miller, Connecticut; Deering G. Smith, New Hampshire; Harry V. Paryzek, Ohio; J. Morrison Hutcheson, Virginia; A. W. Adson, Minnesota; Felix J. Underwood, Mississippi; E. H. Cary, Texas; James R. McVay, Missouri; Robert L. Anderson, Pennsylvania; Edward J. McCormick, Ohio; James P. Wall, Mississippi, and Maurice Hardgrove, Isthmian Canal Zone, and others.

Dr. A. A. Walker, Alabama, moved that the nominations be closed, and the motion was seconded by Dr. George W. Kosmak, New York, and Dr. William A. Weston, Section on Pediatrics, and carried.

Dr. A. A. Walker, Alabama, moved that the Speaker of the House or the Secretary be empowered to cast the vote of this House for the next President-Elect, and the motion was seconded by Dr. H. B. Everett, Tennessee, and carried unanimously.

The Secretary cast the ballot of the House for Dr. Roger I. Lee, Boston, for President-Elect of the American Medical Association for the ensuing year, and the Speaker declared Dr. Lee so elected.

Election of a Vice President

Dr. E. H. Cary, Texas, nominated for Vice President Dr. Stanley J. Seeger, Texarkana, Texas, who has done an excellent job as Chairman of the Council on Industrial Health, and the nomination was seconded by Dr. James C. Sargent, Wisconsin.

Dr. William Weston, Section on Pediatrics, moved that the nominations be closed, and the motion was seconded by Dr. William A. Mulherin, Georgia, and carried.

On motion of Dr. E. H. Cary, Texas, seconded by Dr. James C. Sargent, Wisconsin, and carried, the Secretary cast the ballot of the House for Dr. Stanley J. Seeger, Texarkana, Texas, to serve as Vice President of the American Medical Association for the ensuing year.

The Speaker declared Dr. Stanley J. Seeger duly elected Vice President of the American Medical Association for the ensuing year.

Address of President-Elect Roger I. Lee

Dr. William R. Brooksher, Arkansas, escorted Dr. Roger I. Lee, newly elected President-Elect of the American Medical Association, to the platform and Dr. Lee addressed the House as follows:

Mr. Speaker, Members of the House: I would be far less than human if I were not deeply touched by this tribute. To be President-Elect of the greatest profession in the world in the greatest country in the world is something that is just beyond words. I am particularly touched by the fact that this House of Delegates, with whom I have worked ten years as a Delegate and another ten years on the Board of Trustees, should be the agency which did this. It is one thing to be elected by those who don't know you; it is a particular tribute to be

elected by your friends who know you so well, and I pledge whatever is within me to the medical profession and to the American Medical Association.

Election of Secretary

Dr. Wells P. Eagleton, New Jersey, nominated Dr. Olin West, Chicago, to succeed himself as Secretary of the American Medical Association, and the nomination was seconded by Drs. George W. Kosmak, New York; Edwin S. Hamilton, Illinois; William A. Mulherin, Georgia; Andrew F. McBride, New Jersey; Edward R. Cunniffe, New York; William Weston, Section on Pediatrics; Lloyd Noland, Alabama; John Z. Brown, Utah; H. B. Everett, Tennessee; Robert A. Peers, California, and Walter G. Phippen, Massachusetts, and others.

Dr. A. A. Walker, Alabama, moved that the nominations be closed, and the motion was seconded by Dr. Burt Shurly, Section on Laryngology, Otology and Rhinology, and carried.

Dr. A. A. Walker also moved that the Speaker cast the ballot of the House for Dr. Olin West as Secretary, and the motion was seconded by Dr. Andrew F. McBride, New Jersey, and unanimously carried, and the Speaker cast the ballot of the House for Dr. Olin West and declared him elected to the office of Secretary of the American Medical Association for the ensuing year. Dr. West addressed the House briefly.

Election of Treasurer

Dr. R. L. Sensenich, Board of Trustees, stating that the Board of Trustees is directed by the Constitution to nominate some one for the treasurership, presented the name of Dr. Josiah J. Moore, Chicago, to succeed himself as Treasurer of the Association. The nomination was seconded by Dr. E. S. Hamilton, Illinois.

Dr. G. Henry Mundt, Illinois, moved that the nominations be closed. The motion was seconded by Dr. John Z. Brown, Utah, and carried.

Dr. G. Henry Mundt, Illinois, presented a substitute motion that the House confirm the nomination of the Board of Trustees for Treasurer. The motion was seconded by Dr. William A. Mulherin, Georgia, and carried, and the Speaker declared Dr. Moore elected to the office of Treasurer for the ensuing year.

Announcement of Bombing of Japan

The Secretary read the following message, which was received with applause:

The United Press has just received an announcement by the War Department that B-29 super fortresses of the United States Army Air Force 20th Bomber Command today bombed Japan. This is the first raid on Japan proper since the Doolittle raid in 1942.

Election of Speaker of House of Delegates

With Dr. R. W. Fouts, Vice Speaker, in the Chair, Dr. James Q. Graves, Louisiana, nominated Dr. H. H. Shoulders, Nashville, Tenn., to succeed himself as Speaker of the House. The nomination was seconded by Drs. William Weston, Section on Pediatrics; William A. Mulherin, Georgia; J. B. Lukins, Kentucky, and J. F. Hassig, Kansas, and others.

Dr. George W. Kosmak, New York, moved that the nominations be closed and the motion was seconded by Dr. H. B. Everett, Tennessee, and carried.

Dr. George W. Kosmak moved that the Secretary be directed to cast the ballot of the House for Dr. Shoulders, and the motion was seconded by Dr. Mather Pfeifferberger, Illinois, and carried.

The Secretary cast the ballot of the House for Dr. H. H. Shoulders, Nashville, Tenn., for Speaker of the House of Delegates of the American Medical Association for the ensuing year, and the Vice Speaker declared Dr. Shoulders so elected.

Dr. Shoulders resumed the Chair and addressed the House briefly.

Election of Vice Speaker of House of Delegates

The Speaker resumed the Chair and called for nominations for Vice Speaker of the House of Delegates.

Dr. Robert E. Schluter, Missouri, nominated Dr. Roy W. Fouts of Omaha, Neb., to succeed himself and the nomination

was seconded by Drs. Mather Pfeiffenberger, Illinois, and James Q. Graves, Louisiana, and others.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. George W. Kosmak, New York, and carried, the nominations were closed.

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, and carried, that the Secretary cast the ballot of the House for Dr. R. W. Fouts for Vice Speaker. The Secretary cast the ballot of the House for Dr. Roy W. Fouts, Omaha, to serve as Vice Speaker of the House of Delegates for the ensuing year and the Speaker declared Dr. Fouts duly elected.

Election of Trustees

ELECTION OF TRUSTEE TO SUCCEED DR. ROGER I. LEE

Dr. Edward R. Cunniffe, New York, nominated Dr. Louis H. Bauer, New York, for the office of Trustee of the American Medical Association to succeed Dr. Roger I. Lee, resigned. The nomination was seconded by Drs. George W. Kosmak and J. Stanley Kenney, New York; Holman Taylor, Texas; Harry V. Paryzek, Ohio; Walter G. Phippen, Massachusetts; Robert A. Peers, California; James R. Miller, Connecticut; Arthur R. McComas, Missouri; Lloyd Noland, Alabama, and Robert L. Anderson, Pennsylvania. On motion of Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, seconded by Dr. George W. Kosmak, New York, and carried, the nominations were closed.

On motion of Dr. J. Stanley Kenney, New York, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the Secretary cast the ballot for the election of Dr. Louis H. Bauer as Trustee for a term of five years and the Speaker declared Dr. Bauer so elected.

ADDRESS OF DR. LOUIS H. BAUER

The Chairman presented Dr. Bauer, who addressed the House as follows:

Mr. Speaker and Members of the House: I am somewhat at a loss to know what to say. Naturally I appreciate the honor. I hope that goes without saying. But I want you to know that I also realize that it carries with it a tremendous responsibility and an enormous amount of work. I had the privilege during the past year of sitting in on a few of the meetings of the Board of Trustees when matters pertaining to the Council on Medical Service and Public Relations were under consideration, and I could not help but be impressed with the infinite detail and the very careful consideration which they give to every question which comes before them. I am very proud to be associated for the next five years with a group of men of that caliber. I feel somewhat in a state of tremulation in taking over those duties. It makes me wonder whether I have the necessary qualifications. I know many members of this House who have served a good deal longer than I have and are better qualified for this honor. But if hard work and earnest loyalty to the ideals of American medicine mean anything, I can assure you of that. I just hope that you won't expect me to fill the shoes of Roger Lee. I don't know any one who can do that. But if when this term is over you can say that I have in some small degree approached his stature, then I shall feel well satisfied.

ELECTION OF TRUSTEE TO SUCCEED DR. E. L. HENDERSON

Dr. J. B. Lukins, Kentucky, nominated Dr. E. L. Henderson, Louisville, Ky., to succeed himself as Trustee, and the nomination was seconded by Drs. Walter E. Vest, West Virginia; Louis A. Buie, Section on Gastro-Enterology and Proctology; F. S. Crockett, Indiana; Robert H. Hayes, Illinois; William Weston, Section on Pediatrics, and Thomas A. McGoldrick, New York.

Dr. Robert A. Peers, California, moved that the nominations be closed. The motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried.

On motion of Dr. Louis A. Buie, Section on Gastro-Enterology and Proctology, seconded by Dr. William L. Mullerlin,

Georgia, and carried, the Secretary was instructed to cast the ballot of the House for Dr. E. L. Henderson, Louisville, Ky., to succeed himself as a member of the Board of Trustees.

The Secretary cast the ballot of the House for Dr. Elmer L. Henderson, Louisville, Ky., to succeed himself as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr. E. L. Henderson so elected.

ADDRESS OF DR. E. L. HENDERSON

The Chairman requested Dr. J. B. Lukins, Kentucky, to conduct Dr. Henderson to the platform, after which Dr. Henderson addressed the House as follows:

Mr. Speaker, Members of the House of Delegates: I wish to thank you for the honor which you have bestowed on me and for your expression of continued confidence, and I wish to tell you that I will continue to serve you as I have for the past five years to the best of my ability.

Nominations for Standing Committees

NOMINATIONS BY DR. HERMAN L. KRETSCHEMER, PRESIDENT MEMBER OF THE JUDICIAL COUNCIL

Dr. Herman L. Kretschmer, President, nominated Dr. Edward R. Cunniffe, New York, to succeed himself as a member of the Judicial Council for a term of five years.

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, that the House confirm the nomination, and the motion was seconded by Drs. Thomas M. Brennan and Thomas A. McGoldrick, New York, and Andrew F. McBride, New Jersey, and carried, and the Speaker declared Dr. Cunniffe duly elected a member of the Judicial Council for a term of five years.

MEMBER OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

Dr. Kretschmer nominated Dr. Charles H. Phifer, Chicago, to succeed Dr. J. Gurney Taylor, Milwaukee, as a member of the Council on Scientific Assembly for a term of five years.

On motion of Dr. J. Morrison Hinchelton, Virginia, seconded by Dr. G. Henry Mundt, Illinois, and carried, the nomination was confirmed, and the Speaker declared Dr. Charles H. Phifer, Illinois, duly elected for membership on the Council on Scientific Assembly for a term of five years.

ADDRESS OF DR. EDWARD R. CUNNIFFE

Mr. Speaker, Members of the House: I wanted to tell you a story which I told in New York in a recent election. Winston Churchill, when he was attending public school in England, won a medal for excellence in one of the studies that he was doing at the time, and he wrote to his mother apprising her of the fact. She wrote back and said "I am very glad to hear of your success, Winston. I know you don't deserve it, but try to live up to it."

ADDRESS OF DR. CHARLES H. PHIFER

Mr. Speaker, Mr. President, Members of the House of Delegates: I am most grateful to all of you for the honor you have conferred on me and I will do all that I can to fill the position to which I have been elected.

NOMINATIONS BY THE BOARD OF TRUSTEES

MEMBER OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS TO SUCCEED DR. CHARLES GORDON HEYD

Dr. R. L. Sensenich for the Board of Trustees reminded the House of the section in the Constitution and By-Laws directing the Board of Trustees to submit nominations for a member of the Council on Medical Education and Hospitals and that it has been the practice to nominate two persons for that place on the Council as a vacancy occurs. The Board of Trustees therefore placed in nomination the name of Dr. Charles Gordon Heyd to succeed himself, and also the name of Dr. Fred M. Smith of Iowa City.

The Tellers spread the ballot and the Secretary announced that 149 Delegates had registered present, and that 139 votes were cast, of which Dr. C. Gordon Heyd received 83 and Dr. Fred Smith 47.

The Speaker declared Dr. Charles Gordon Heyd elected by the House to membership on the Council on Medical Education and Hospitals for a term of seven years.

THE COUNCIL ON MEDICAL SERVICE AND
PUBLIC RELATIONS

The Speaker stated that according to a rule of the House adopted by the House on Monday, a ballot had been prepared by the Board of Trustees. The Board of Trustees is charged with placing in nomination before the House for membership on the Council on Medical Service and Public Relations these names:

Dr R L Sensenich for the Board of Trustees announced that there were difficulties in the manner of presentation because there were six places to fill and the By-Laws specifically stated that the term of membership on the Council shall be three years, provided at the end of the first year there shall be an election of two members for one year, two for two years and two for three years and that the House will have to decide on how it will select the various terms of office. However, after the first year the Board of Trustees shall present to the House of Delegates for Election to membership to the Council a list of three nominations for each vacancy. It was further provided that these must be selected according to geographic distribution. The Board of Trustees gave considerable study as to how best to present this and therefore prepared for the House a ballot on which there were three nominations each for six places and they were geographically arranged.

The names are (arranged alphabetically in each group) for group 1 Drs Joseph Londrigan, Hoboken N J, Thomas A McGoldrick, Brooklyn, and Walter G Phippen, Salem, Mass., group 2, Drs John H Fitzgibbon, Portland Ore, William R Molony, Los Angeles, and Raymond L Zech, Seattle, group 3, Drs William R Brooksher, Fort Smith Ark, Wingate M Johnson, Winston-Salem, N C, and W S Leathers, Nashville, Tenn., group 4, Drs A W Adson, Rochester Minn, E S Hamilton, Kankakee, Ill, and Thomas I Thornton, Waterloo, Iowa, group 5, Drs Carl McCaskey, Indianapolis, E J McCormick, Toledo, Ohio, and Walter I West, Huntington, W Va, and group 6, Drs John W Amuse, Denver, Forrest L Loveland, Topeka, Kan, and James R McVay, Kansas City, Mo, one man in each group on the ballot to be voted for.

The Speaker reread the Report of the Reference Committee on Rules and Order of Business that the House had adopted on Monday, after which Dr Holman Taylor, Texas, moved that the House cast its ballots in accordance with the grouping as set out by the Trustees. The motion was seconded by Dr Thomas M Brennan, New York and carried.

The Speaker appointed as additional tellers Drs James C Sargent, Wisconsin, James M Flynn, New York, and Stephen E Gavin, Wisconsin.

Death of Dr. John T. Murphy

The Secretary made the following announcement:

Mr Speaker, Members of the House. It is with great regret that I have to announce to the House that a gentleman who has served this Association very faithfully for many years, Dr John T. Murphy, Secretary of the Section on Radiology, has died today. Dr Murphy is known to many members of this House and to thousands of physicians throughout the United States and has rendered most devoted service for all these years as Secretary of our Section on Radiology.

Dr William A Mulherin, Georgia, moved that the tellers be requested to retire from the room and make a careful count of the ballot and bring back a report on it. The motion was seconded by Dr Thomas A Pitts, South Carolina, and carried.

Election of Affiliate and Associate Fellows

NOMINATIONS FOR AFFILIATE FELLOWSHIP APPROVED
BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

The Secretary presented the following nominations for Affiliate Fellowship, properly approved by the Council on Scientific Assembly, which, on motion of Dr Thomas M Brennan, New York, seconded by Dr William A Mulherin, Georgia, and carried, were confirmed:

Abel, William C, Columbia, S C
Ayer, Thomas H, Westboro, Mass
Baker, Charles H, Chilhowie, Va
Berge, F E, Long Beach, Calif
Brennemann, Joseph S, Reading
Vi (nomination from Illinois
State Medical Society)
Brown, John R, Hollywood, Calif
Burkholder, J T, Chicago
Chipman, Ernest D, San Francisco
Cole, Lewis G, White Plains, N Y
Commons, E L, Los Angeles
Cooke, W L, Columbus, Ga
Culbert, William L, New York
Davis, George E, New York
Dayton, Hughes, Irvington, N Y
Dutton, Mary L, San Francisco
Edwards, Ralph F, Bigfork, Mont
(nomination from Minnesota)
Ellis, Frederick W, Newton Centre,
Mass
Flanders, Louis W, Dover, N H
Glandman, Alexander, New York
Goodman, Charles, New York
Gray, G M, Kansas City, Kans
Hackney, F J, Centralia, Wash
Hawkes, Charles E, Greenville,
R I
Hicks, I Clay, Huntington, W Va
Hill, Roland, St Louis
Kanu, Ulysses S, New York
Kingsbury, Jerome, New York
Lamberton, R T, Denver
Ledbury, John Wm, Uxbridge,
Mass

Levens, Nathan N, Boston
Lynch, Charles F, Springfield,
Mass
MacDonald, D F, Taunton, Mass
MacLachlin, Charles, New Rock
ford, N D
Manierre, John T, Chicago
McPherson, George E, Amherst,
Mass
Messinger, M P, Oakfield, N Y
Mueller, Anton D, Chicago
Neff, Robert L, Joplin, Mo
Oates, Charles E, North Little
Rock, Ark
Oliver, Ellwood, Pine Plains, N Y
Patterson, Robert Q, Little Rock,
Ark
Powers, Everett, Carthage, Mo
Rowell, Hubert N, Berkeley, Calif
Schall, John H, Brooklyn
Seelig, M G, St Louis
Shipp, Augustus C, Little Rock,
Ark
Shoog, A L, Kansas City, Mo
Slaughter, Emma Y, Lowell, Mass
Smith, Edwin M, Sr, Chicago
Smith, William H, Boston
Sondern, Frederic E, New York
Sprun, Kate C, St Louis
Walker, Moses R, Berkeley, Calif
(nomination from Nevada)
Watkins, John G, Little Rock, Ark
Weinberger, C F, Chicago

NOMINATIONS FOR ASSOCIATE FELLOWSHIP

The Secretary presented the following nominations for Associate Fellowship approved by the section indicated, which were confirmed on motion of Dr John J Masterson, New York, seconded by Dr Thomas A McGoldrick, New York, and carried.

SECTION ON PRACTICE OF MEDICINE

Wood W Barry, Jr, Clayton, Mo

SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

Ryan, Edward J, D D S, Evanston, Ill

SECTION ON PEDIATRICS

Anderson, George King, Evanston, Ill

SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS	
Ansbacher, Stefan, Dr Sc, Rich- mond Hill 18, N Y	Herwick, Robert T, Washington, D C
Ellis, Fred W, Ph D, Chapel Hill, N C	Pickchaun, Ardzoony, Gilkerton, Texas
Hart, E Ross, Philadelphia	Way, Edward L, Washington, D C

SECTION ON PATHOLOGY AND PHYSIOLOGY

Halpert, Bela, Oklahoma City

Lewis, Howard B, Ann Arbor, Mich

SECTION ON NERVOUS AND MENTAL DISEASES

Moore, Thomas V, Brookland, D C

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Rostenberg, Adolph, Jr, Washington, D C

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE
AND PUBLIC HEALTH

DeNosaquo, Norman, Chicago

Kerlan, Irvin, Washington, D C

Place of 1947 Annual Session

The Speaker appointed as additional tellers, so that the House could go on with the selection of the Place of 1947 Annual Session, Drs William Weston, Section on Pediatrics; William A Mulherin, Georgia; Thomas A Pitts, South Carolina, and H B Everett and E G Wood, Tennessee.

Dr R L Sensenich of the Board of Trustees reported that it was the opinion of the Board that it would be well to remind the House at this time that the 1947 session, which is the session for which you will now receive invitations, marks the one hundredth anniversary of the history of the American Medical Association. The Board has for some time past had in preparation extensive plans for the proper celebration of this anniversary in the session to be held in 1947. It is to be hoped at least that by 1947 either the war will be over or conditions will have so changed that it may be possible to entertain distinguished men from all over the world, men distinguished in scientific investigation, in education, in the practice of medicine and in all of those things which will be

of interest to us. In other words, in order that that session may be properly accommodated, it seemed important that the House give consideration to the needs of such meeting and that the city selected to entertain that particular meeting in 1947 should have sufficient available facilities for the housing properly of the Scientific Assembly and the presentation of addresses by these distinguished guests, but also it would be wisely known in advance that there would be sufficient housing accommodations at that meeting to celebrate properly the anniversary of the American Medical Association.

There have been invitations received, one from St. Louis and one from Atlantic City. I believe that the gentlemen representing those cities will present their invitations.

Dr. Robert E. Schlueter, Missouri, presented the advantages of St. Louis as a meeting place and extended an invitation to the Association to meet there in 1947.

Dr. Andrew F. McBride, New Jersey, cited the advantages of Atlantic City and invited the Association to meet in Atlantic City, N. J.

On request of the Speaker the Tellers spread the ballot.

To a request for the information the Secretary stated that the 1945 session will be held in New York City, and the 1946 session in the city of San Francisco.

The Speaker declared the ballot closed and requested the Tellers to proceed with the count.

The Secretary announced that 111 votes had been cast, of which Atlantic City received 80 and St. Louis 31.

On motion of Dr. Robert E. Schlueter, Missouri, duly seconded and carried, the selection of Atlantic City as the 1947 place of annual session was made unanimous, and the Chairman declared that Atlantic City had been selected as the place of session in 1947.

Address of Dr. Benvenuto R. Dino

The Chairman called on Dr. Benvenuto R. Dino, personal physician to the president of the Philippines, who addressed the House as follows:

Mr. Speaker, Members of the House: I wish to express my grateful appreciation for this distinct privilege to address you again this afternoon. I recall with pleasure that two years ago in Atlantic City I spoke to you and expressed the gratitude and the loyalty of the Filipino people to the government and people of America. Two years have passed and many developments have taken place, and, at this time, at your closing session of the House of Delegates it is significant to me that you remember the Philippines, because as you do you also remember freedom.

My friends, I wish to inform you that the Filipinos today are all over the battlefronts of the world. Thousands of them are in the armed forces, in the Army, the Navy and the Coast Guard, in the Merchant Marine; thousands are in agriculture, especially in California and in the Pacific Northwest; many thousands are in essential jobs and industries. And back home the battle of the Philippines is still on in the hills of Luzon, in the Visayan Islands of Panay, in Cebu, Negros and Mindanao. These facts have been transmitted by official Japanese broadcasts. These are things for you and for all of us to think about. In spite of the cruelties and the sufferings of this war, sometimes I am thankful because we, the Filipinos, are given another chance to prove to the government and the people of the United States our loyalty and our gratitude.

Election of Members of the Council on Medical Service and Public Relations

Dr. Henry S. Ruth, Section on Anesthesiology, reported for the Chairman of Tellers on nominations by the Board of Trustees for members on the Council on Medical Service and Public Relations the following result.

	Votes		Votes
Dr. Londrigan	11	Dr. Adson	74
Dr. McGoldrick	96	Dr. Hamilton	55
Dr. Phippen	29	Dr. Thornton	4
Dr. Fitzgibbon	102	Dr. McCaskey	12
Dr. Molony	21	Dr. McCormick	84
Dr. Zech	10	Dr. Vest	37
Dr. Brocksner	42	Dr. Amesce	21
Dr. Johnson	20	Dr. Loveland	12
Dr. Leathers	76	Dr. McVay	99

The Chairman announced the election of Dr. Thomas A. McGoldrick, New York, having received 96 votes, as the member selected in group 1; the election of Dr. John H. Fitzgibbon, having received 102 votes, as the member selected in the second group; the election of Dr. W. S. Leathers, having received 70 votes, as the member selected in group 3; the election of Dr. A. W. Adson, having received 74 votes, as the member selected in group 4; the election of Dr. E. J. McCormick, having received 84 votes, as the member selected in group 5, and the election of Dr. James R. McVay, having received 99 votes, as the member selected in group 6.

As to terms, under the rules adopted by the House, the two receiving the highest number of votes are elected each for a three year term, namely Drs. John H. Fitzgibbon, Oregon, having received 102 votes, and James R. McVay, Missouri, having received 99 votes; the two receiving the next highest number of votes, each for a two year term, namely Drs. Thomas A. McGoldrick, New York, having received 96 votes, and E. J. McCormick, Ohio, having received 84 votes, and the two receiving the next highest number of votes, each for a one year term, namely Drs. A. W. Adson, Minnesota, having received 74, and W. S. Leathers, Tennessee, having received 70 votes. The Chairman declared those gentlemen elected to these respective terms.

On motion of Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, duly seconded and carried, the House adjourned sine die at 2:55 p. m.

REGISTRATION AT CHICAGO

The total registration at Chicago was 7,284. Below are summaries of the registration by sections and by states.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Chicago session was characterized by the emphasis put on war medicine. The United States Army, the United States Army Air Forces and the United States Navy presented noteworthy exhibits of their own and lent generous aid in men and materials to other features of the meeting.

The Scientific Exhibit was reduced to about half its usual size because of the limitation of space in the Palmer House, and it was necessary to move the Motion Picture Program to the Morrison Hotel. The caliber of the exhibits which were shown was very high, and great credit is due to the exhibitors who, under the difficulties of wartime, were able to assemble such excellent material.

There were four Special Exhibits subsidized by the Board of Trustees.

The Special Exhibit on Fractures, under the auspices of a committee composed of Dr. Kellogg Speed, Chicago, chairman, Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia, was presented again this year. The United States Army cooperated in supplying materials, as well as soldiers who served as patients in the exhibit, and a group of thirty physicians and two nurses participated throughout the week in the demonstrations. A pamphlet describing the exhibit was distributed.

The Special Exhibit on the Treatment of Burns was organized by a committee consisting of Dr. Stanley J. Seeger, Texarkana, Texas, chairman, Capt. Ernest W. Brown (MC), U. S. Navy, and Capt. Joseph E. Hamilton, M. C., A. U. S. The exhibit covered the following subjects under the direction of the physicians indicated:

1. Treatment of War Burns, Capt. Joseph E. Hamilton, M. C., A. U. S.
2. Local Treatment of Burns, Dr. Roy D. McClure, Henry Ford Hospital, Detroit.
3. Treatment of Burns: General Care of the Burned Patient, Dr. Henry N. Harkins, Johns Hopkins University School of Medicine, Baltimore.
4. Establishment of a Skin Cover Following a Thermal Burn, Dr. Earl C. Padgett, University of Kansas School of Medicine, Kansas City, Mo.
5. Chemical Burns of the Eyes, Dr. Alan C. Woods, Johns Hopkins Hospital, Baltimore.
6. Electric Burns, Dr. Hart Ellis Fisher, Chicago.
7. Prevention of Burns in the Navy, Capt. Ernest W. Brown (MC), U. S. Navy (retired).

In addition, a group of physicians assisted in the demonstrations throughout the week, and pamphlets covering all phases of the treatment of burns were distributed.

The Special Exhibit on Chemotherapy and Infectious Diseases was presented under the auspices of a committee composed of Dr. Chester S. Keefer, Boston, chairman, Dr. Henry E. Meleney, New York, and Dr. Austin E. Smith, Chicago. Emphasis was placed on tropical diseases, and a group of physicians who had special experience in foreign countries with these diseases was present throughout the week to demonstrate the exhibit. A pamphlet describing the exhibit was distributed.

The Special Exhibit on Rehabilitation was presented by the Council on Industrial Health and the Council on Physical Therapy of the American Medical Association in cooperation with representatives of the Army, Navy, Veterans Administration and Federal Security Agency. The exhibit emphasized the current importance of rehabilitation and reemployment and covered the following subjects under the direction of the physicians indicated:

1. Fractures, Dr. Kellogg Speed, Chicago.
2. Amputations, Capt. Henry H. Kessler (MC), U. S. N. R.
3. Lame Backs, Dr. Frank R. Ober, Boston.
4. Hard of Hearing, Dr. William E. Grove, Milwaukee.
5. Tuberculosis, Dr. Leroy U. Gardner, Saranac Lake, N. Y., and Mr. Holland Hudson, New York.
6. Heart Disease, Dr. William D. Stroud, Philadelphia, and Dr. Rufus B. Crain, Rochester, N. Y.
7. Psychiatry, Dr. George S. Stevenson, New York.
8. Community Relations, Dr. Harold A. Vonachen, Peoria, Ill.
9. Reemployment, Dr. Max R. Burnell, Flint, Mich.

Special demonstrators were in attendance during the week.

A group of exhibits on Tropical Medicine attracted much attention and received special commendation from the Committee on Awards.

The Section on Practice of Medicine presented nine exhibits, one of which received an award. Dr. Thomas C. Garrett, Philadelphia, was the section representative.

The Section on Surgery, General and Abdominal, presented ten exhibits, two of which received awards, including a Silver Medal. The section representative was Col. Grover C. Penberthy, M. C., A. U. S.

The Section on Obstetrics and Gynecology had eight exhibits, one of which received an award. Dr. Frederick H. Falls, Chicago, was the section representative.

The Section on Ophthalmology had two exhibits, one of which received an award. The committee representing the section was composed of Dr. Georgiana D. Theobald, Oak Park, Ill., chairman, Lieut. Col. Derrick Vail, M. C., A. U. S., and Dr. A. B. Reese, New York.

The Section on Laryngology, Otology and Rhinology presented seven exhibits, one of which received an award. The section representative was Dr. Paul H. Holinger, Chicago.

The Section on Pediatrics had four exhibits. Dr. Sterling H. Ashmun, Dayton, Ohio, was the section representative.

The Section on Experimental Medicine and Therapeutics presented nine exhibits, three of which received awards, including a Gold and a Silver Medal. The section representative was Dr. Robert W. Wilkins, Boston.

The Section on Pathology and Physiology presented ten exhibits, three of which received awards, including a Gold Medal. The section representative was Dr. Frank W. Konzelmann, Philadelphia.

The Section on Nervous and Mental Diseases had five exhibits, one of which received an award. Dr. F. P. Moersch, Rochester, Minn., was the section representative.

The Section on Dermatology and Syphilology presented six exhibits, one of which received an award. Dr. Hamilton Montgomery, Rochester, Minn., was the section representative.

The Section on Preventive and Industrial Medicine and Public Health had ten exhibits, one of which received an award. Dr. Paul A. Davis, Akron, Ohio, was the section representative.

The Section on Urology had three exhibits. Dr. John H. Morrissey, New York, was the section representative.

The Section on Orthopedic Surgery showed four exhibits, two of which received awards. Dr. Fremont A. Chandler, Chicago, was the section representative.

The Section on Gastro-Enterology and Proctology presented three exhibits, one of which received a Bronze Medal. Dr. Grant H. Laing, Chicago, was the section representative.

The Section on Radiology had two exhibits, one of which received a Bronze Medal. The section representative was Dr. S. W. Donaldson, Ann Arbor, Mich.

The Section on Anesthesiology had six exhibits, two of which received awards. The section representative was Dr. E. A. Rovenstine, New York.

Other features of the Chicago session included the question and answer conferences on Rheumatic Fever presented by the Section on Pediatrics in cooperation with the Rheumatic Fever Committee of the American Academy of Pediatrics, and on Heart and Peripheral Vascular Disease presented by the Section on Practice of Medicine in cooperation with the American Heart Association.

Fifty motion picture films were shown on a regular schedule in the Casino at the Morrison Hotel. Most of the films were shown twice during the week.

Twenty-three papers which were read before the sections of the Scientific Assembly were correlated with the exhibits in the Scientific Exhibit.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report:

GROUP I

(Awards in Group I are made for exhibits of individual investigation, which are judged on the basis of originality and excellence of presentation.)

The GOLD MEDAL to William H. Feldman, H. Corwin Hinshaw and Frank C. Mann, Mayo Foundation, Rochester, Minn., for the exhibit on Chemotherapy of Tuberculosis.

The SILVER MEDAL to Robert H. Williams, Harvard Medical School and Boston City Hospital, Boston, for the exhibit on Thiouracil in Thyrotoxicosis.

The BRONZE MEDAL to J. A. Roth, A. C. Ivy and A. J. Atkinson, Northwestern University Medical School, Chicago, for the exhibit on Effect of Caffeine on the Stomach.

CERTIFICATES OF MERIT, Group I, are awarded to the following (alphabetically arranged):

Paul N. Harris and K. K. Chen, the Lilly Research Laboratories, Indianapolis, for exhibit on Experimental Liver Injury.

George N. Papanicolaou, Herbert F. Traut and Andrew A. Marchetti, Cornell University Medical College, New York, and Joe V. Meigs, Maurice Fremont-Smith, Ruth M. Graham, Israel Kapnick and Lois T. Janzen, Harvard Medical School, Massachusetts General Hospital, Boston, for the exhibit on the Vaginal Smear in the Diagnosis of Cancer.

R. H. Rigdon, University of Arkansas School of Medicine, Little Rock, for the exhibit on Pathologic Lesions Occurring in Human and Experimental Malaria.

H. S. Van Orstrand and Robert Hughes, Cleveland Clinic, Cleveland; J. M. deNardi, Lorain, Ohio, and Morris G. Carmody, Painesville, Ohio, for the exhibit on Industrial Diseases in the Beryllium Industry.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of H. J. Corper, National Jewish Hospital, Denver, on the Transdermal Tuberculin Test.

That of A. C. Hilding, Duluth, Minn., on the Production of Negative Pressure in Respiratory Tract by Ciliary Action—Probable Relation to Postoperative Atelectasis.

That of Mildred Trotter, Virginia S. Lanier, Gordon S. Letterman and Howard E. McKnight, Department of Anatomy, Washington University School of Medicine, St. Louis, on Continuous Caudal Analgesia; Pertinent Anatomic Features.

That of Charles S. White, Jacob J. Weinstein and J. Lloyd Collins, George Washington Medical School and Gallinger Hospital, Washington, D. C., on Protein Metabolism and the Use of Protein Digest in Surgery; Preparation of Plasma by Sedimentation by a New Method.

GROUP II

(Awards in Group II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation and correlation of facts.)

The GOLD MEDAL to Armand J. Quick, Marquette University School of Medicine, Milwaukee, for the exhibit on Determination of Prothrombin.

The SILVER MEDAL to Keith S. Grimson, Duke University, Durham, N. C., for the exhibit on Paravertebral Sympathectomy for Hypertension.

The BRONZE MEDAL to Leo G. Rigler, University of Minnesota, Minneapolis, Henry S. Kaplan, Lieutenant, M. C., A. U. S., and Daniel L. Fink, Captain, M. C., A. U. S., for the exhibit on Pernicious Anemia, Benign Polyps and Carcinoma of the Stomach.

CERTIFICATES OF MERIT, Group II, are awarded to the following (alphabetically arranged):

Urban H. Eversole, Leo V. Hand and Morris J. Nicholson, the Lahey Clinic, Boston, for the exhibit on Spinal Anesthesia.

Harry Gold and McKeen Cattell, Cornell University Medical College, New York, for the exhibit on Recent Developments in Digitalis.

J. Q. Griffith Jr. and Wilfred E. Fry, University of Pennsylvania, Philadelphia, for the exhibit on Papilledema; Mechanism and Clinical Applications.

J. E. M. Thomson, University of Nebraska, Lincoln, for the exhibit on Local Shock—A Vasomotor Phenomenon Occurring in Certain Severe Injuries of the Extremities.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of C. W. Emmons, National Institute of Health, United States Public Health Service, Bethesda, Md., on Fungi of Dermatologic Importance.

That of John J. Fahey, Chicago, on the Circulation of the Femoral Head.

That of E. S. Gurdjian and John E. Webster, Major, M. C., A. U. S., Wayne University College of Medicine and Grace Hospital, Detroit, on Traumatic Intracranial Hemorrhage.

That of Kurt Lange and Linn J. Boyd, New York Medical College, New York, on the Use of Fluorescein to Determine the Adequacy of Circulation.

CERTIFICATE OF APPRECIATION

A Certificate of Appreciation is awarded to J. Ramos e Silva, Escola de Medicina e Cirurgia, Rio de Janeiro, Brazil, for his contribution on Brazilian Dermatoses.

SPECIAL COMMENDATION

Special commendation is given to the group of exhibits on tropical medicine, as well as to the question and answer conferences on rheumatic fever and heart and peripheral vascular diseases.

The Committee on Awards wishes to offer appreciation and commendation to the United States Army, the United States Army Air Forces and the United States Navy for their excellent exhibits and for their cooperation in the over-all success of the Scientific Exhibit at the 1944 Session.

SUBSIDIZED EXHIBITS

The Committee on Awards commends highly the Special Exhibits on Fractures, the Treatment of Burns, Chemotherapy and Infectious Diseases, and Rehabilitation which are sponsored by the Board of Trustees of the American Medical Association.

COMMENTS

The Committee regrets its inability to have included in the awards a consideration of the motion pictures which are being shown this year in the Casino at the Morrison Hotel. Because of unusual space and time considerations, many pictures could not be exhibited prior to the final meeting of the Committee on Awards.

The representatives to the Scientific Exhibit from the sixteen sections have rendered invaluable service to the Committee on Scientific Exhibit and to the Director of the Scientific Exhibit in encouraging the presentation of exhibit material of special interest and merit. Only the limitation in the number of awards available prevented official recognition of a large number of exhibits of undoubted merit.

Finally, the Committee on Awards desires to compliment the Director of the Scientific Exhibit of the American Medical Association, Dr. Thomas G. Hull, for having dealt in a splendid fashion with the many difficulties encountered in arranging the Scientific Exhibit under the most trying conditions of wartime.

VINCENT W. ARCHER, University, Va., Chairman.
DANIEL S. CUNNING, New York.
THOMAS G. ORR, Kansas City, Kan.
JOHN W. SCOTT, Lexington, Ky.
RALPH M. WATERS, Madison, Wis.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. Res. 592 has been agreed to by the House of Representatives, directing the House Committee on Education to make a study of the effect on the colleges and universities in the United States of (1) reduction in enrolment and in faculties as a result of service by students and faculty members in the armed forces or in other war activities and (2) recent curtailment and prospective further curtailment of Army and Navy training programs in such colleges and universities. This committee will be authorized to formulate such legislation as it deems appropriate for presentation to the House. H. R. 1506 has passed the House and Senate, a bill to amend the Pay Readjustment Act of 1942. Among other amendments, this legislation will permit service in the Medical Reserve Corps to be counted for pay purposes. H. R. 4615 passed the House, a bill to establish, for the investigation and control of tuberculosis, a division in the United States Public Health Service. In the Senate, this bill was included as an amendment to H. R. 4624, the bill consolidating and revising the laws relating to the United States Public Health Service, and was enacted by the Senate in that form. H. R. 4624 has passed the Senate with amendments, and those amendments have been agreed to by the House, a bill consolidating and revising the laws relating to the United States Public Health Service. H. R. 4881 has passed the House and Senate, amending the federal narcotic laws to include Isonipeaine. H. R. 4899 has been agreed to by the conferees, providing appropriations for the Department of Labor, the Federal Security Agency and related independent agencies for the fiscal year ending June 30, 1945. As agreed to in conference, this bill appropriates \$42,800,000 for a continuation of the E. M. I. C. program, extends the benefit of the program to Army aviation cadets and provides that 2.5 per cent of the amounts allotted to the states may be used for administrative purposes. H. R. 4967 has passed the House and Senate and the conference report has been agreed to, making appropriations for the military establishment for the fiscal year ending June 30, 1945. This bill provides, among other things, that no appropriation contained in it shall be available for any expense incident to educating persons in medicine, including veterinary, or dentistry, if any expense on account of their education in such subjects was not being defrayed out of appro-

priations for the Military Establishment for the fiscal year 1944 prior to June 7, 1944. The foregoing proscription is subject to an exception that nothing in it "shall interfere with compliance with the provisions of law authorizing the detail of officers and enlisted men of any component of the Army of the United States as students, observers and investigators as contemplated by section 127 (a) of the National Defense Act, approved June 3, 1916, as amended."

Bills Introduced.—H. R. 5079, introduced by Representative Dondero, Michigan, provides for vocational training and retraining programs for the occupational adjustment and readjustment of veterans returning from military service, war workers demobilized from war production plants, and for other youth and for adults. H. R. 5103, introduced by Representative Rogers, Massachusetts, provides for the establishment of a permanent Nurse Corps in the Veterans' Administration. H. R. 5128, introduced by Representative Miller, Missouri, proposes the deferment in each calendar year under the Selective Training and Service Act of not less than 6,000 medical students and not less than 4,000 dental students.

DISTRICT OF COLUMBIA

Changes in Status.—H. R. 3150 has passed the House, proposing to amend the healing arts practice act of the District of Columbia so as to modify the requirement that an applicant applying for a license to practice must have practiced in another jurisdiction for not less than two years. As a substitute for this requirement, the bill would provide (1) that the applicant must have practiced in another jurisdiction for not less than one continuous year out of three years immediately preceding the date of his application and (2) that that one year's continuous practice may be either private, institutional or governmental, or a combination thereof. H. R. 4867 has passed the House, extending the health regulations of the District of Columbia relating to restaurants to such establishments operated by the government.

Bill Introduced.—H. R. 5065, introduced, by request, by Representative Randolph, West Virginia, proposes to require examination and laboratory tests for syphilis, gonorrhea and tuberculosis of all applicants for marriage licenses before the issuance thereof in the District of Columbia.

WOMAN'S AUXILIARY

Florida

The Florida auxiliary held its state convention April 13-14 at St. Petersburg, with Mrs. F. W. Krueger, president, presiding.

Georgia

Mrs. W. T. Randolph, president-elect of the Georgia auxiliary, has written the following message to members: "A call is being made on all doctor's wives to enlist in auxiliary work for the duration. Every community looks to the doctor's wife to be an authority on subjects concerning health and education. She is obligated to speak authoritatively, and there is no better source of information than the medical auxiliary, since its object, as set forth in the constitution, is 'to extend the aims of the medical profession to all organizations which look to the advancement of health and education; to assist in the entertainment of all state, district, county and other medical meetings; to promote acquaintanceship among physicians' families that fellowship may increase.' Every physician's wife owes it to herself and to her husband to become affiliated with the auxiliary to the medical society in some way."

Illinois

The annual convention of the Illinois auxiliary was held at the Palmer House, Chicago, May 16-17. Mrs. Frederick Tice, Oak Park, was convention chairman.

Iowa

At a recent meeting of the Iowa auxiliary, Mrs. Jay C. Decker of Sioux City was installed as president and Mrs. Soren S. Westly of Manly was chosen president-elect. Mrs. William S. Reilly of Red Oak is the retiring president.

The Sioux City auxiliary had a tea recently at which election of officers took place. Many projects were discussed and plans made to cooperate with the Woodbury County Medical Society in its activities concerning the Wagner-Murray-Dingell bill.

Kansas

Mrs. Leo J. Schaeffer has been elected president of the Kansas auxiliary and has chosen the national program of "Health and Postwar Planning" as the state's slogan for 1944-1945.

Mississippi

The Mississippi auxiliary held its state convention May 9-10. Mrs. Eben J. Carey, national president, was the guest speaker at the annual luncheon. Mrs. J. L. Clark is the new president.

North Carolina

The North Carolina Auxiliary held its twenty-second annual convention at Pinehurst May 1-3. A novel feature was the presentation of door prizes at the meeting of a war bond and many "warsages." Mrs. L. T. Pace of Greenville was the president.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSANS

District Meetings.—At a meeting of the Ninth Councilor District Medical Society in Harrison, June 7, the speakers included Dr. Merlin J. Kilbury, Little Rock, on "Interpretation of Laboratory Findings"; Dr. Wesley J. Ketz, Batesville, "Treatment of Urinary Infections," and Dr. Ruth E. Lesh, Fayetteville, "Torsion of Ovarian Cysts in Children." Dr. Joseph F. Shuffield, Little Rock, president of the state medical society, also spoke.—The Fifth Councilor District Medical Society was addressed on May 16 in Magnolia by Drs. Joe D. Nichols, Atlanta, Texas, on "Intravenous Anesthesia" and Wiley R. Buffington, New Orleans, "Certain Ocular Manifestations Resulting from Systemic Diseases."

CALIFORNIA

Osteopath Sentenced for Abortion.—Clyde A. Pierson, D.O., San Bernardino osteopath, was recently sentenced by Judge Charles L. Allison to serve two to five years in San Quentin, after his motion for a new trial on three counts of abortion had been denied. Through counsel, Pierson served notice of appeal, and a stay of execution was granted pending its hearing. Judge Allison increased bail from \$2,500 to \$10,000, and the osteopath promptly posted the amount in cash.

Illegal for Barber to Administer Eye Drops.—In an opinion on May 23 Attorney General Robert W. Kenny ruled that it is illegal for a barber to administer eye tonic drops, it is reported. Treatment of the eyes, the opinion said, either with medicine or with surgery, is limited to physicians and surgeons. The opinion was to C. E. Rynearson, secretary of the state board of barber examiners. The ruling said "Many eye tonics are drugs, under California law, and the barber administering them may be guilty of practicing medicine without a license. The use of any product classified as a drug by those not qualified to administer it could, in certain instances, lead to dangerous results. Barber shops may pass along a dangerous infection."

Incidence of Meningitis in San Francisco.—That the incidence of epidemic meningitis is increasing in San Francisco is evidenced by a report of Dr. Jacob C. Geiger, director of public health, San Francisco, appearing in *California's Health*, April 29. In 1942 a total of 33 cases with 10 deaths was reported. In 1943 a total of 153 cases, the highest number ever to be reported in one year in San Francisco, was recorded, with case reporting reaching a peak in March 1943 with 28 cases, more than had been previously recorded in a single month. The first twelve weeks of 1944, 64 cases were recorded, or 42 per cent of the annual total for 1943. For the first three months of 1944 the disease increased more than 52 per cent in the state as a whole as compared with the first three months of 1943; 423 cases in civilians were reported in the state during this period of 1944 as compared with 277 during the corresponding period of 1943. The total number of civilian cases recorded in the state was 207 in 1942, 927 in 1943 and 423 during the first quarter of 1944.

DELAWARE

Society News.—Dr. William H. Perkins, dean and professor of preventive medicine, Jefferson Medical College of Philadelphia, discussed "Tropical Diseases of Concern to the Home Front" before the New Castle County Medical Society and the Delaware Academy of Medicine, Wilmington, May 16. Dr. Henry J. Tumen, Philadelphia, addressed the society April 18 on "Acute Infectious Hepatitis."

DISTRICT OF COLUMBIA

Personal.—Dr. Robert Lomax Wells was recently named medical director of the Chesapeake and Potomac Telephone Company to succeed Dr. William Cabell Moore, who had held the office since March 1922. The latter will continue in private practice.

Dr. Ramsey Resigns as Head of the Department of Obstetrics.—Dr. Herbert P. Ramsey has resigned as executive officer of the department of obstetrics at George Washington University School of Medicine but will remain on the

faculty as clinical professor of obstetrics and gynecology according to *Medical Annals*. Dr. Radford Brown, professor of obstetrics and gynecology, will be acting executive officer until August 31.

ILLINOIS

Dearholt Medal Awarded to Dr. Bosworth.—Dr. Robt. Bosworth, medical director of Pleasant View Sanatorium East St. Louis, was given the Dearholt Medal during annual meeting of the Mississippi Valley Conference on Tuberculosis at its meeting in Chicago, May 10. The citation accompanying the award emphasized Dr. Bosworth's contribution to the development of sanatoriums for tuberculous patients and "a pioneer in the development of standards for outpatient work." The medal is awarded annually for "a marked special service to tuberculosis control in the conference area." Dr. Bosworth is a former president of the Mississippi Valley Conference on Tuberculosis.

Chicago

Aleck Bauer Dies.—Aleck Bauer, founder of Bauer Black, division of the Kendall Company, died June 11, aged 84.

Mac Cahal Returns to Chicago.—Mr. Mac F. Cahal, who resigned as executive secretary of the American College of Radiology to accept a similar position with the Southwestern Medical Foundation, Dallas, has resigned the latter position to return to his post with the American College of Radiology. Mr. Cahal will resume his former activities about August.

Special Society Elections.—At the meeting of the Chicago Society of Internal Medicine, May 22, Dr. Lee C. Galloway was named president and Dr. George E. Wakerlin vice president. Dr. Howard L. Alt was reelected secretary-treasurer.—Dr. James E. Fitzgerald was chosen president-elect of the Chicago Gynecological Society at its annual meeting, May 19, and Dr. William J. Dieckmann was installed as president. Other officers include Drs. Ralph A. Reis, vice president, Henry Buxbaum, treasurer, and Herbert E. Schmitt, secretary.—Dr. Theophil P. Grauer was chosen president of the Chicago Urological Society at its meeting, May 25, Dr. James W. Merricks vice president, and Dr. Russell D. Herold was reelected secretary-treasurer.

MICHIGAN

New Building for Penicillin Laboratory.—Plans are under way to build a \$15,000 penicillin laboratory in Lansing. It is the hope of the Michigan Department of Health eventually to add penicillin to the list of products distributed free to the physicians of the state.

Dr. Vanderslice Joins Mott Foundation.—Dr. David A. Vanderslice has resigned as director of the school health service of the Ann Arbor Public Schools to become medical consultant to the Flint Public Schools and director of the Charles Stewart Mott Foundation health center. The new appointment was effective July 1.

University News.—Approval has been given to a contract between the federal Office of Scientific Research and Development and Wayne University College of Medicine, Detroit, to conduct a study on the influence of oral administration of sodium lactate solution. The government will provide \$7,500 to cover the cost of the project, which will be carried out under the direction of Dr. John W. Hirschfeld, assistant professor of surgery at the college of medicine.

Wayne University Initiates Sigma Xi Members.—At the first annual initiation of the Wayne University Chapter of the Society of Sigma Xi, May 26, Dr. Milton H. Erickson, director of psychiatric research and training, Eloise Hospital and Infirmary, discussed "Psychiatry as a Wartime Science." William H. Pyle, president of the chapter, was toastmaster at the banquet. New initiates in the society included Drs. William L. Brosius, Sylvester E. Gould, Gordon B. Myers, Paul H. Noth, Thomas L. Patterson, Ph.D., and Dr. Erickson.

Society Serves Families of Servicemen.—Families of servicemen who are unable to obtain the services of their regular family physician may call the Medical Information Center of the Wayne County Medical Society under a new plan recently adopted by the society. The service includes the making available of names of members of the society in the neighborhood of the inquirer and the provision of service to the family at either a minimum or a no cost basis. More than 100 members of the society have registered to take emergency calls day and night, while an additional 600 have offered free aid to servicemen's families. Physicians will be available within a 3 mile radius of every Wayne County family. A map at the Medical Information Center will be pinned at doctors' homes and offices, from which the attendant will select the convenient physician for any call.

MINNESOTA

Personal.—Dr. Sidney A. Slater, Worthington, was presented with a gold wrist watch at a recent meeting of the Minnesota Public Health Association in recognition of his six years of service as president of the association.

Hospital News.—Heron Lake Hospital Association is the name of the newly incorporated hospital administration taking over the former Southwestern Minnesota Hospital at Heron Lake. The board of trustees is headed by Dr. Alfred G. Chadbourn.

Dr. Hill Succeeds Dr. Harrington.—Dr. Frank J. Hill, Bismarck, since November 1940 health officer of North Dakota, has been appointed health commissioner of Minneapolis to succeed Dr. Francis E. Harrington, who will retire on June 19 (THE JOURNAL, Dec. 11, 1943, p. 980).

Osteopath Ends Life While on Trial for Manslaughter.—James O. Humbert, Minneapolis, a licensed osteopath, was found dead in a hotel room, May 7, with an artery slashed in his left wrist. The coroner of Hennepin County, Dr. Russell R. Heim, Minneapolis, recorded the death as a suicide. Humbert was on trial in the district court of Hennepin County on an indictment charging him with the crime of manslaughter in the first degree. According to the Minnesota State Board of Medical Examiners, Humbert was indicted on a charge of performing an abortion.

NEBRASKA

Rheumatic Disease Program.—The state division of crippled children's services has opened a program for the care of children with rheumatic fever in Douglas and Sarpy counties. Children from these counties who are under 21 years of age and are suffering from or suspected to be suffering from rheumatic fever may be referred for diagnosis and consultation service. If they are found to be in need of care and their parents are unable to provide such care they will be accepted for treatment. Diagnostic clinics will be held at the University of Nebraska Hospital. Cooperating agencies concerned in the program are the University of Nebraska Hospital and Dispensary, Omaha Visiting Nurse Association, state department of health nurses assigned to Sarpy county, Nebraska Society for Crippled Children, and the Douglas County Assistance Department. It is hoped that the program will serve as a demonstration of the need of and possibilities for the care of children with or suspected of having rheumatic fever.

NEW YORK

Changes in Health Officers.—Dr. Henry C. Lapp has resigned as health officer of North Tonawanda, a position he had held for twenty-two years; he had been a member of the board of health for twenty-five years. Dr. Edward M. Battgasser, Buffalo, has been appointed health officer of Lancaster to succeed Dr. Clarence B. Mackey, who is ending twenty-three years in the position. Dr. James C. Boland, Binghamton, has been appointed health officer of Troy.

Graduate Lectures.—"Penicillin Therapy" was the title of a graduate lecture presented recently under the auspices of the state medical society and the state department of health. Dr. James E. McCormack, New York, gave the lecture before the Broome County Medical Society, Binghamton, May 16, Richard C. Arnold, Surgeon, U. S. Public Health Service, before the Medical Society of the County of Warren, Glens Falls, June 15. Dr. Frederick N. Marty, Syracuse, delivered the lecture before the Medical Society of the County of St. Lawrence, Potsdam, June 22. Dr. McCormack also addressed the Westchester County Medical Society, White Plains, June 20, and Dr. William J. Orr, Buffalo, the Cattaraugus County Medical Society in Allegany, June 22.

New York City

Hospital News.—The Herbert N. Straus mansion at 9 East Seventy-First Street will be transformed into a convalescent hospital as an adjunct to St. Clare's Hospital at 415 West Fifty-First Street.

Personal.—Henry C. Sherman, Ph.D., who recently resigned as chief of the bureau of human nutrition and home economics of the U. S. Department of Agriculture, has returned to his position as executive officer of the department of chemistry at Columbia University.

James Bryan Executive Secretary of New York County Society.—James E. Bryan, White Plains, has resigned as executive secretary of the Westchester County Medical Society to accept a similar position with the Medical Society of the County of New York, effective in September.

Gonococcus Culture Service—Penicillin Treatment.—

Physicians in private practice are now offered the opportunity of utilizing the gonococcus culture service of the New York City Department of Health. Specimens will be taken for culture from patients with gonorrhea or suspected of having gonorrhea. This service is available to patients of private physicians who cannot afford private laboratory service. At present examinations are made only at the central clinic, 130 Leonard Street, Manhattan.—Sulfonamide resistant gonorrheal patients may be referred for treatment with penicillin to the Leonard Street clinic, where treatment may be obtained for these patients without cost, irrespective of their economic status.

NORTH CAROLINA

State Medical Election.—Dr. Oren Moore, Charlotte, was chosen president-elect of the Medical Society of North Carolina at its annual meeting in Pinehurst and Dr. Paul F. Whitaker, Kinston, was installed as president. Other officers include Drs. William H. Smith, Goldsboro, and Zack D. Owens, Elizabeth City, vice presidents. Dr. Roscoe D. McMillan, Red Springs, is secretary-treasurer. The society voted to meet in Pinehurst again in May 1945.

OHIO

Hard of Hearing Society Changes Name.—The Cleveland Association for the Hard of Hearing, with headquarters at Garfield House, has changed its name to the Cleveland Hearing Center.

School History to Be Published.—The "Centennial History of the School of Medicine of Western Reserve University," prepared by Frederick C. Waite, Ph.D., professor emeritus of histology and embryology, was recently submitted for publication.

Civilian Physicians Awarded Service Ribbons.—A group of forty-seven physicians were presented with service ribbons at a dinner June 7 after they were cited for meritorious service by the War Department. The physicians were honored for having helped the Army and Navy examine more than 300,000 men since the induction center opened in Cleveland in January 1941, according to the Cleveland Press.

Ninety Years of Age.—Dr. Edwin W. Mitchell, who graduated at the Medical College of Ohio, now known as the University of Cincinnati College of Medicine, in 1882 and who served as a member of the staff through the school's development, observed his ninetieth birthday, May 29. Dr. Mitchell has served as professor of materia medica and therapeutics, professor of pediatrics and professor of theory and practice of medicine and is now professor emeritus.

PENNSYLVANIA

State Survey of Mentally Ill.—Dr. Howard K. Petry, Harrisburg, chairman of the committee on mental hygiene of the state medical society, was appointed chairman of a board appointed recently to survey state institutions for the care of the mentally ill.

Licenses Revoked.—The state board of medical education and licensure announced that the following licenses were revoked at a meeting of the board on April 26:

Dr. Francis J. Trygar, Philadelphia, because of conviction in the Philadelphia County Courts, upheld by the Superior Court of Pennsylvania, of criminal abortion.

Dr. Christos N. Spanos, Pittsburgh, because of conviction in the Philadelphia County Courts, upheld by the Superior Court of Pennsylvania, of criminal abortion.

Dr. Morton Reese, Mount Clemens, Mich., because of conviction in the Federal Court at Detroit of violation of the federal narcotic laws.

Dr. Alexander J. P. Conlen, Allentown, because of grossly unethical conduct by which he induced citizens to become a prey to exploitation.

Mrs. Mary Ferrari, midwife, Scranton, because of conviction in the Lackawanna County Court of criminal abortion.

The license of Dr. Modestus William S. Buechele, formerly of Altoona, now in the armed forces, was restored.

Philadelphia

Personal.—Dr. R. Manning Clarke, clinical professor of medicine at the College of Medical Evangelists, Los Angeles, has been appointed to a similar position at the Woman's Medical College of Pennsylvania.

Fund for Free Hospitalization of Cancer Patients.—The Dorothy Case Blechschmidt Cancer Prevention Clinic of Doctors Hospital was recently presented with a \$10,000 fund for free hospitalization of cancer patients of the clinic. The clinic was organized two years ago and is named for Dr. Blechschmidt, who serves as its chief of staff. The clinic is financed by a membership of almost 1,000 women. No salaries are paid, for all the service is voluntary.

TEXAS

Narcotic Violations.—Dr. Gus Levin, Fayetteville, on March 14 pleaded guilty in the U. S. District Court in Houston to a violation of the federal narcotic law. He was sentenced to imprisonment for a term of eighteen months, which was probated for a period of five years. Dr. Charles Hudson Turner, Dallas, pleaded guilty in the U. S. District Court at Dallas, May 11, to a violation of the federal narcotic law in that he forged the name of another physician to a narcotic prescription. Sentence was suspended and Dr. Turner was placed on probation of one day, according to the federal deputy commissioner of narcotics.

Trees Dedicated to Dr. Carrell.—Two pecan trees in the Latin American quarter of Dallas were recently dedicated to the memory of the late Dr. William B. Carrell by Pan American Round Table No. 1, Dallas, of which the late physician's wife is director. Mrs. T. B. Griffith, assistant director of Pan American Round Table No. 1, presented the trees to Mayor Woodall Rodgers and the city of Dallas and to Mexican Consul Luis Perez-Abreu as well as to the Latin Americans. Special tribute was paid to the work done with crippled children by Dr. Carrell, who at the time of his death in February was professor of orthopedic surgery at the Southwestern Medical Foundation.

Closed Psychopathic Hospital to Be Opened as Venereal Disease Center.—The state board of control and the state board of health have an agreement to operate the Galveston State Psychopathic Hospital, closed since August 1943, as a rapid treatment center for venereal disease in cooperation with the U. S. Public Health Service. Facilities at the university and the fever therapy department of the John Sealy Hospital have been made available to the state board of health to assist in the new development. According to an announcement from Chauncey D. Leake, Ph.D., dean of the University of Texas School of Medicine, Galveston, it is believed that the center may become available for special research in new means of syphilis control as developed by Dr. Chester N. Frazier, professor of dermatology and syphilology at the school, and that the center may be utilized for special studies in psychiatry under the direction of Dr. Titus H. Harris, professor of neuropsychiatry, and Dr. Jack R. Ewalt, associate professor of neuropsychiatry.

VERMONT

Personal.—Dr. William J. McNamara, Fair Haven, was recently named supreme physician of the Knights of Columbus; he will be located in New Haven, Conn.

University News.—Dr. Otto Loewi, research professor of pharmacology, New York University College of Medicine, delivered the annual Sigma Xi Lecture at the University of Vermont College of Medicine, Burlington, April 28. His subject was "Chemical Mediation of Nerve Impulses." On April 27 Dr. Loewi also addressed the Oster Clinical Society at the college on "Control of Endocrine Secretions." The clinical society was addressed in Burlington, May 25, by Abraham Wikler, P. A. Surg., U. S. Public Health Service Reserve, on "Problems of Drug Addiction." Dr. Louis S. Goodman, professor of pharmacology and physiology at the university, was guest speaker at the Grafton County Medical Society, Wells River, April 26. His subject was "The Advancing Frontiers in Medical Therapeutics." Dr. Philip D. Woodbridge, professor of anesthesia, Temple University School of Medicine, Philadelphia, gave a lecture demonstration to the students and staff of the University of Vermont College of Medicine, Burlington, May 27, on "Problems of Clinical Anesthesia."

WASHINGTON

Society News.—At a meeting of the Walla Walla Valley Medical Society in Walla Walla, May 11, Dr. Charles R. Garrett was chosen president. Dr. Harlan P. Kahler is secretary. Dr. Richard D. Reekie, Spokane, discussed "Water Balance in Pregnancy."

Personal.—Dr. Willis E. Smiek has resigned as deputy county health officer of Kittitas. Dr. Percy F. Guy, Seattle, has been named assistant health officer of King County, succeeding Dr. Bryan Newsom, county epidemiologist, who resigned April 1 to enter private practice. It was stated that the position of assistant health officer will include most of the former duties of Dr. Newsom as epidemiologist.

Statewide Mental Program for Rehabilitation of Service Men.—The Washington State Medical Association and the state department of health are planning to inaugurate sometime in August a statewide mental health program for

the rehabilitation of discharged service men not covered by the Veterans Bureau. A committee on mental hygiene has been appointed by the state medical association to act in advisory capacity to the state health department. The plans call for the employment of three teams composed of three each, a psychiatrist, a psychologist and a social worker trained in psychiatry, with possibly one of the teams stationed in eastern Washington and two on the west side. The board of trustees of the state medical association approved the program proposed by the state department of health with the provision that the committee on mental hygiene act in an advisory capacity.

Proposed Medical School.—The board of trustees of the Washington State Medical Association has appointed a committee to study the recommendation to establish a medical school for the University of Washington, Seattle. The committee is to make a report to the house of delegates of the state association. Members of the committee include the following physicians:

David Metheny, Seattle, chairman.
Homer D. Dudley, Seattle, 1st district.
Albert P. Duryee, Everett, 2d district.
Milton P. Graham, Aberdeen, 3d district.
George W. Cornett, Yakima, 4th district.
George H. Anderson, Spokane, 5th district.
Warren B. Penney, Tacoma, 6th district.
Vernon W. Spickard, Seattle, president, state association, ex officio.
Albert J. Bowles, Seattle, secretary, state association, ex officio.
David C. Hall, Seattle, University of Washington Health Department, ex officio.

A subcommittee was also named composed of Drs. Metheny, Dudley, Duryee and Hall. If the regents of the university and the state medical association are agreeable on the establishment of the school, it is believed that the two groups will jointly initiate legislation for the appropriation of funds in the coming session of the state legislature when it meets in January 1945, according to *Northwest Medicine*.

GENERAL

Life Expectancy Gains.—The average length of life in American people had advanced in 1942 to 64.82 years, the highest figure on record, a gain of 15½ years since 1900, according to statisticians of the Metropolitan Life Insurance Company. An announcement from the company points out that a greater proportion of persons now than ever before will live to age 65, the normal retirement age. In fact it was stated, more than two thirds of persons now between ages 25 and 35 will reach age 65, while almost three fourths now 45 years old and four fifths of the persons now 55 will attain that age. After attaining age 65, the average person can still look forward to living 13.12 years longer.

Voluntary Tests for Medicine.—In Atlanta, Ga., 15 men at the federal penitentiary are ill with malaria in a voluntary test supervised by the National Research Council, U. S. Public Health Service, Army and Navy medical officers, newspapers reported June 11. A group of 15 other prisoners are reporting to the prison laboratory daily for blood tests, it was stated. The men volunteered to act as "guinea pigs" in this study. They will be under observation for eighteen months (The Journal, March 18, p. 786). Another newspaper report, May 22, states that twenty-six physicians, nurses and students from the University of California Medical School, San Francisco, submitted to various forms of torture in the preparation of a "pain map" of the body. It was stated that the project involved the piercing of muscles with sharp instruments and drilling of bones. The subjects not only bore their pain but also gave a running account of their sensations, it was reported.

Industrial Hygiene Groups Choose Officers.—Officers of the National Conference of Governmental Industrial Hygienists chosen at its meeting in St. Louis in May include Mr. Manfred Bowditch, director, division of occupational hygiene, Massachusetts Department of Labor and Industries, Boston, chairman; Dr. Leslie W. Foker, director, division of industrial health, Minnesota Department of Health, Minneapolis, vice chairman, and Senior Sanitary Engineer J. J. Bloomfield, chief, field operations section, industrial hygiene division, U. S. Public Health Service, Bethesda, Md., secretary-treasurer. At a meeting of the American Industrial Hygiene Association also in St. Louis Dr. Robert A. Kehoe, Kettering Laboratory of Applied Physiology, University of Cincinnati College of Medicine, was chosen president-elect and Mr. Bloomfield was inducted into the presidency. Other officers inducted were Edgar C. Barnes, industrial engineer, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., secretary, and John B. Littlefield, industrial hygienist, American Rail Shoe and Foundry Company, Chicago, treasurer.

Society News.—The Biological Photographic Association will hold its fourteenth annual meeting in Binghamton, N. Y., September 7-9, under the presidency of Ferdinand R. Harding, Boston. The association is a nonprofit organization for the study of photography as applied to medicine, dentistry and the biologic and natural sciences. Additional information may be obtained from Anne Shiras, secretary of the association, University Office, Magee Hospital, Pittsburgh 13.—The ninth annual assembly of the International College of Surgeons will be held October 3-5 at the Benjamin Franklin Hotel, Philadelphia. The program will be devoted to war, rehabilitation and civilian surgery. The assembly is sponsored by the United States chapter of the college, of which Dr. Thomas A. Shallow, Philadelphia, is president.—The Association of Military Surgeons of the United States will hold its annual meeting at the Pennsylvania Hotel, New York, November 2-4. Col. Charles M. Walson, M. C., U. S. Army, Headquarters Second Service Command, Governors Island 4, New York, is chairman of the convention and program committees.—The National Medical Association will hold its fiftieth annual convention in St. Louis, August 14-17, as the guest of the Mound City Medical Forum. Dr. John T. Givens, 1108 Church Street, Norfolk, Va., is general secretary of the association.

Meningococcal Meningitis in the United States.—In 1943 the United States experienced the highest incidence of meningococcal meningitis during the thirty years since the public health service began the collection of morbidity data of this disease in 1914, according to *Public Health Reports*. Preliminary reports show that a total of 17,974 was reported by the state health authorities of forty-eight states and the District of Columbia, an incidence of 13.4 per hundred thousand of population. The next highest reported incidence was in 1929, when 10,551 cases were reported in forty-six states and the district, giving an incidence rate of 8.7 per hundred thousand of population. *Public Health Reports* shows that the incidence rate for the country as a whole was 50 per cent higher in 1943 than in 1929, the highest rates being recorded in the New England, Middle Atlantic and Pacific areas. Figures for total deaths from meningococcal meningitis during 1943 were not available at the time of this report, but on the basis of the average of the monthly rates for a 10 per cent sample of death certificates, issued by the Bureau of Census, and the incidence rate the case fatality ratio was 16.4. While not strictly comparable, but probably more nearly complete, the reports for 1943 for thirty-two cities scattered throughout the United States give a case fatality of 18.4 per cent. The ratio for California was 16.9, while for that for New York City was 16. The report indicates that the greater part of the recent reduction in the fatality for meningococcal meningitis is due to the introduction of chemotherapy, emphasis being placed on the effectiveness of sulfonamide therapy.

Grants for Poliomyelitis Research.—Twenty-seven grants totaling \$1,128,770 for work on infantile paralysis were announced June 21 by the National Foundation for Infantile Paralysis. All grants in effect July 1 will strengthen the foundation's program of seeking ways and means of alleviating suffering of victims of the disease and methods emphasizing the search for a preventive or cure. The total appropriations include three long term programs of five years each, two of which, totaling \$495,000, are to improve knowledge in the field of physical medicine. These two grants provide for the establishment of two "units for research in physiology as related to physical medicine," the larger of which will be at the University of Minnesota Medical School, Minneapolis, with a grant of \$320,000. Under a grant for \$175,000 the second unit will be established at Northwestern University Medical School, Chicago, one of the first institutions to adopt a department of physical medicine. The grant will assist the university in expanding its program of scientific investigation and training of investigators and teachers in the field of physical medicine. A third long term grant of \$325,000 will go to the University of Michigan School of Public Health, Ann Arbor, to finance and operate an expanded virus study unit. The work will include a program of field and laboratory investigation of poliomyelitis and other virus diseases, including a study of the disease where it becomes established in a community and the manner in which it spreads and the maintenance of a virus laboratory particularly adapted and available for use by clinicians working with this disease. The program will include a search for a rapid indirect method of recognizing the poliomyelitis virus by use of the high speed centrifuge,

Tiselius apparatus and other biophysical equipment available at the Michigan Department of Health laboratories and with the electron microscope and laboratory facilities at the university, thus obtaining a purified and concentrated virus. It is hoped that in this manner methods may be developed from these purified materials for rapid identification of the virus in diagnosis of the infection. The Michigan project began about three years ago. The enlarged unit will continue to be under the direction of Dr. Thomas Francis Jr., professor of epidemiology and chairman of the department. At the University of Minnesota a unit will be set up for studies in the area of physiologic investigation of the basis for physical medicine procedures applicable to poliomyelitis and other diseases. The problems involved will call for the coordinated activities in the field of neurophysiology and other branches of physiology, biochemistry, pharmacology, neuropathology, neuroanatomy, clinical neurology, pediatrics, orthopedics and physical therapy. The general direction of the proposed investigation will be assigned to a committee consisting of the heads of the departments concerned in the University of Minnesota Medical School. The chairman of the committee will be Dr. Maurice B. Visser, professor and head of the department of physiology. The Northwestern grant will intensify research in basic medical sciences in the varied phases in the field of physical medicine. Under this grant studies will be pursued relative to the use in diagnosis and treatment of electricity, light, heat, cold, exercise, rest and other physical measures. The effects of these forces on nerves and muscles damaged by diseases such as infantile paralysis will make up a major part of the study. While many of the projects have been in operation for the past several years with aid of the national foundation, it now seems advisable to the university to enlarge the scope of the program by including all departments concerned on a cooperative basis, making possible many lines of investigation which otherwise could not be undertaken. The unit will be under the direction of Dr. Andrew C. Ivy, Nathan Smith Davis professor and head of the department of physiology and pharmacology. Of the total of \$1,128,770 the amount allotted for work on "after-effects" is \$536,500, on virus research \$392,400 and on education \$199,870.

Government Services

Allocation of Quinidine

On June 9 the War Production Board amended the order governing allocation of cinchona bark and cinchona alkaloids to permit the delivery of quinidine to an ultimate consumer on the receipt of a prescription signed by a person who is licensed to prescribe drugs. Only physicians licensed to practice medicine were permitted to prescribe quinidine prior to this revision. Quinidine may be used only for the treatment of cardiac disorders, according to the War Production Board.

Senior Specialist in Health Education Named

Lester A. Kirkendall, Ph.D., educational consultant, Venereal Disease Education Institute, Raleigh, N. C., has been temporarily assigned within the Federal Security Agency from the United States Public Health Service to serve as senior specialist in health education in the division of physical education and health activities in the U. S. Office of Education. He will serve schools and colleges in fields given such designations as social hygiene and "human relations."

Distribution of Lanham Funds

The Federal Works Agency has allotted \$2,532,266 of Lanham Act Funds. A total of \$1,865,528 was allotted to nineteen war public works projects in twelve states, with an estimated cost of \$2,566,984. Contributions amounting to \$666,638 were approved for fifteen war public services projects in ten states. Nine of the war public works projects are for nurses' homes and training facilities. Included also are projects for the construction of sewer, school, child care, hospital and recreation facilities. The war public services projects provide assistance in the maintenance and operation of school, child care, recreation, garbage and police facilities.

The British Medical Association and the White Paper

In a previous letter (*THE JOURNAL*, March 25, p. 941) the white paper on a national health service, issued by the government, was summarized and the immediate reaction of the British Medical Association was given. The council has now put forward for the consideration of the profession a statement of policy which is intended to be the basis of discussion at meetings of the whole profession. The medical profession is declared to be in complete agreement with the government's aim to ensure that every one shall be able to obtain all the advice and treatment needed in matters of health and that the country's full resources are brought to bear on reducing ill health. The profession, particularly in the last quarter of a century, has again and again pressed on the government developments to this end, but without avail. It is natural that public interest in health should be heightened in time of war, but it is ironic that the government should begin to display a lively interest in organizing medical services at a time when the medical profession and its organizations are almost wholly preoccupied with the problems of war. As a result of recruitment for war service, doctors in civilian practice are heavily overworked. Many of the younger members of the profession who are vitally concerned with these proposals are in the fighting services, and effective consultation with them is difficult. A controversial issue has been raised at a time when the energies of the profession, like those of the whole community, should be directed to one objective—winning the war. There is suspicion that these proposals found their first inspiration in a desire to control an independent profession in order to control certification and thus the disposal of social security funds. The council of the association detects in the white paper a "trend of the times," a move toward planned state control. But the council feels that the state should spare from its bureaucratic intentions a form of human activity which, in an atmosphere of independence and freedom, has made more progress than it could possibly have made under theegis of the state.

The Council makes the following criticisms of details: The proposed central administration is unsatisfactory. The Ministry of Health is left responsible for a number of functions only remotely associated with health. For example, the ministry is left responsible not only for such problems of housing as are clearly related to health but also for supervising the local authorities in actual construction, which is a matter for architects, builders and engineers. Side by side with the Ministry of Health is proposed an advisory body, the Central Health Council, to represent medical practice and teaching, hospital organization and other professional matters. This conforms to the pattern of advisory bodies set up in recent years, of which many have proved useless. They have been façades to protect ministers rather than to advise them. The association cannot accept as an appropriate advisory body to present and effect medical opinion one which is appointed by the minister and which reports only through him. Such a body, as far as its medical members are concerned, should be appointed by the profession. Further, both Parliament and the public are entitled to know what advice has been tendered and whether it has been accepted or not.

At a press conference Dr. H. G. Dain, chairman of the council of the British Medical Association, said that the council had expressed approval of the general principles of the white paper but objected to many of the proposals. The proposed adminis-

trative structure was uncoordinated and chaotic, it was felt. Moreover, no provision was made for the profession to be democratically represented on the advisory bodies or for it to be able to make its advice and views freely known to Parliament and to the public. The voluntary hospitals would in time be submerged, the council feared, which was not in the public interest. Only one type of health center, the communal surgery, was proposed. No provision was made for experiment with other types, such as the diagnostic center. The doctors working in the health centers would be remunerated by salary or similar arrangement; the profession regards this as an attempt to introduce by insidious means a state salaried service, to which it is opposed because it is not prepared to substitute obedience to the state for loyalty to the patient. Remuneration should be related to the amount of work done and not determined by status, it is claimed.

Lord Dawson, president of the British Medical Association, added that there was no disagreement with the principles of a comprehensive health service, which had been advocated by the profession for years. The fundamental fault of the white paper, he said, was that it tried to see too far, to stretch out into the years ahead. At no time was it more difficult than it is now, Lord Dawson stated, to look into the conditions of the future. The program instead should concentrate on what is essential as a foundation; he put first the bringing together of curative and preventive medicine, between which there is a wide gap.

The correspondence columns of the *British Medical Journal* show widespread concern and dissatisfaction with many of the proposals in the white paper. The annual representative meeting of the association will begin on July 18, when the white paper will be the predominant subject for discussion. For this purpose a negotiating committee is to be appointed. It is recommended that this should consist of thirty members, sixteen to represent the British Medical Association, three each the Royal Colleges of Physicians and Surgeons, two the Royal College of Obstetricians and Gynecologists, three the Royal Medical Scottish Corporations, two the Society of Medical Officers of Health and two the Women's Medical Federation.

The Use of Gas Gangrene Antitoxin

The *Army Medical Department Bulletin* points out that the incidence of gas gangrene in the African campaigns of the war has been as high as that in France in the last war and the mortality was a black spot in the otherwise satisfactory recovery rate from wound infections. One of the principal means of improvement is greater use of gas gangrene antitoxin. The conditions that call for injection of prophylactic antitoxin are extensive laceration of muscle, as in compound fracture, obvious contamination of the wound with soil, clothing or other foreign bodies, interference with blood supply (as by tourniquet or tightly packed dressing) and delayed surgical treatment. Wounds of the buttocks and legs are those most frequently associated with the development of gas gangrene, and it must be remembered that small surface wounds may mark the entry of missiles which cause deep, extensive muscle damage, the *Bulletin* points out.

Whenever possible antitoxin should be given intravenously, so that an effective concentration of antibody may be immediately available. If intravenous administration is impossible, antitoxin should be given intramuscularly into healthy tissue. The subcutaneous route should never be used, and there is no advantage in injecting the dose into the region around the wound. For either route the prophylactic dose is the same—the amount of polyvalent antitoxin containing 9,000 units of *Clostridium welchii* antitoxin. This contains other antitoxins against such anaerobes as *Clostridium oedematis maligni* and *Clostridium septicum*. A decision as to whether or not to repeat the prophylactic dose calls for clinical judgment in the light of conditions in the wound and the general picture.

Therapeutic administration is called for urgently at the earliest signs of infection. These may be no more than a feeling of weight in the limb or stump, local pain and swelling, quickening of the pulse or altered mental outlook. In an established case, antitoxin should be given intravenously; when suitable it may be given in intravenous drip with blood, plasma or saline solution. In exceptional circumstances there may be no alternative to intramuscular administration. The initial dose should contain not less than 27,000 units of C.I. welchi antitoxin and needs repetition at intervals of four to six hours according to the condition of the patient. No figure can be given for the total dosage which may be necessary to neutralize the toxemia. Successful chemotherapy with penicillin, sulfonamides or other drugs does not lessen the need for large doses of antitoxin. The risk of severe allergic reactions is no greater than from any other antitoxin and is almost negligible if refined (pepsin treated) antitoxin is used. But, as with all antitoxins, epinephrine should be at hand for injection in case of reaction, the article concludes.

BRAZIL

May 10, 1944.

Cultivation of Cinchona in Brazil

The Division of Vegetal Production of the Department of Agriculture has just published a monograph by the agricultural technologist A. Caminha Filho reviewing all the attempts to cultivate the cinchonas in Brazil since the first experiments in 1868, in the high plateau of Teresopolis, under the patronage of the late emperor Pedro II until the present large scale attempts in the state of São Paulo under the direction of Luiz A. Nucci, agricultural technologist. In spite of the fact that this is where the cinchona plants originated, South America depends on importation for all the quinine it needs. In Brazil, where a large campaign against malaria is now developing, cultivation of the cinchonas is a problem of the utmost importance. As Mr. Caminha Filho points out, the agricultural exploitation of the plant should be studied and begun at once and increased as rapidly as possible. For this purpose he suggests the creation of a specialized service in the Division of Vegetal Production with the cooperation of the Institute of Agricultural Experimentation. According to the biology of the plant, the monograph suggests as convenient places for the initial culture the National Park of Itatiaia, the National Park of the Orgãos Mountain and the high plateau of Friburgo. According to the author, the initial plantations should include a total of at least 800 acres.

Pollen Allergy

In a previous letter (*THE JOURNAL*, Jan. 23, 1943) reporting the work of Dr. Ernesto Mendes of São Paulo, it was pointed out that allergic conditions with such a seasonal character that one could assume pollens to be their cause are not found in Brazil. Dr. Mendes believes that the extremely low incidence of pollen allergy is due to environment rather than to individual peculiarities, as potent allergenic plants are few in this country and meteorologic conditions do not favor high concentrations of pollen in the air. The pollens of potent allergenic plants were found to be fewer than 15 per cubic centimeter at that time. Since then new studies have been undertaken and several papers have been published that cast more light on this problem. Among these studies the most important are those carried out by Dr. A. Oliveira Lima of Rio de Janeiro and Dr. J. B. Greco of Bello Horizonte, state of Minas Geraes. They claim that the rarity of pollinosis in Brazil is explained by several causes, among them the scant interest of physicians in this subject and errors of diagnosis. (Many cases of seasonal pollen rhinopathy are simply labeled common colds.) Another factor is the predisposition typified by the low sensitivity of Brazilians

to the pollen of *Lithrea moleoides*. A large number of American patients sensitive to *Rhus toxicodendron*, as reported in a letter from Shelmire to Oliveira Lima, were also sensitive to the toxiallergenic fraction of the Brazilian *Lithrea*. Greco reports results obtained by him and by Oliveira Lima in sixteen Brazilian cities in the east central section of the country, including Rio de Janeiro, Campinas in the state of São Paulo, Salvador in the state of Bahia and thirteen others in the state of Minas Geraes. He reports the existence of a short, typical pollen season from the middle of May to the middle of June (autumn in the Southern Hemisphere). The only important plants of allergenic activity pertain to the gramineous family, particularly the fatty grass *Melinis minutiflora*.

Brief Items

Dr. C. E. Turner of the Massachusetts Institute of Technology and a staff member of the Division of Health and Sanitation of the Office of the Coordinator of Inter-American Affairs has spent several days in Rio de Janeiro visiting the services of health education. He delivered an address at a special meeting of the Brazilian Society of Hygiene and was entertained by this association during his stay in the city.

Dr. J. Caiado de Castro of Rio de Janeiro died a few days ago at the age of 37. Dr. de Castro was an able surgeon and laryngologist who had a notable record in the field of bronchoscopy and esophagoscopy and in the extraction of foreign bodies from the esophagus, the trachea and the bronchi. His death was deeply felt by his colleagues of the Department of Hospitals of the city of Rio de Janeiro, where, in the exercise of his activity, he had performed more than 5,000 tonsillectomies and more than 2,000 extractions of foreign bodies from the respiratory and digestive tracts.

Dr. Armando Tavares, professor of medicine at the medical school of Salvador, state of Bahia, died at the age of 50. Dr. Tavares was one of the leading specialists in tuberculosis, in which field he had published several important contributions.

Dr. Charles Philippe Leblond of McGill University has spent a few days in Rio de Janeiro. He read a paper on "The Iodine in the Thyroid" in which he brought into focus, in particular, the transformations undergone by this substance as shown by radioactive iodine.

A cablegram from Lima, Peru, reports the good results of the use of penicillin prepared at the Instituto Oswaldo Cruz of Rio de Janeiro and sent by air mail through the Brazilian embassy in Lima for the treatment of a desperate case of septicemia.

Dr. Erasmo Gaertner, professor of surgery at the medical school of Curitiba, state of Paraná, spent a few days at Rio de Janeiro to visit some important medical institutions of the city. Specially invited by the medical board of the Misericórdia Hospital, Dr. Gaertner read a paper, with demonstrations, on the surgical treatment of aneurysms.

Marriages

EDWIN A. HENDRY, Portland, Ore., to Miss Gladys H. Scott of North Bennington, Vt., in New York, February 19.

JOSEPH M. COPPOLETTA, Cliffside Park, N. J., to Miss Dorothea M. Ellis Carousis in New York, June 11.

RICHARD ELI HEDRICK, Winston-Salem, N. C., to Miss Carol Clinton Reid of Columbia, S. C., June 6.

JOHN WELDON WILLIAMS JR. to Miss Laura Ruth Veal, both of Augusta, Ga., May 20.

EDWARD B. McCABE, Carbondale, Pa., to Miss Mary M. Hunt of Archbald, May 20.

RUSSELL W. BERNHARD to DR. ELIZABETH THORNTON, both of San Francisco, June 11.

Deaths

Henry James Spencer * New York; Columbia University College of Physicians and Surgeons, New York, 1913; formerly associate professor of clinical medicine at Cornell University Medical College; diplomate of the National Board of Medical Examiners, of which he had been past president; specialist certified by the American Board of Internal Medicine; fellow of the New York Academy of Medicine, associate member of the Harvey Society, fellow of the American Association for the Advancement of Science; member of the American Heart Association, New York Tuberculosis and Health Association and the American Institute of Nutrition; assistant attending physician to the Hudson Street Branch of the New York Hospital from 1917 to 1919; served as assistant attending physician, attending physician, president of the medical board and consulting physician at the Willard Parker Hospital; associate attending physician, New York Hospital; visiting physician and director, second medical division, Bellevue Hospital; associate visiting consultant in medicine at the Children's Hospital, Randall's Island, from 1920 to 1928; formerly on the staff of the Lincoln Hospital; organizer and chief, department of metabolic diseases, Cornell Clinic, from 1921 to 1931; contract surgeon attached to the Second Service Army Command; died June 11, aged 60.

Erasmus Darwin Fenner * New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1892; professor of orthopedics and surgical diseases of children, emeritus, at his alma mater; he joined the teaching staff in 1893, serving as associate professor of the diseases of children from 1903 to 1907, when he became head of a newly created department of orthopedics; resigned from this position in 1927; past president of the Orleans Parish Medical Society; member of the Clinical Orthopaedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; specialist certified by the American Board of Orthopaedic Surgery, Inc.; captain, medical reserve corps, U. S. Army, June 15, 1917; assigned to duty with Base Hospital number 24, Aug. 31, 1917; liaison officer, 12th Region, June 1918-January 1919; major in the medical corps Nov. 9, 1918; honorably discharged April 24, 1919; decorated Officer d'Académie by French government; in 1942 honored at ceremonies at the Charity Hospital and given a silver cup for his fifty years of untiring service to the institution; chief, independent division of orthopedics and fractures and senior visiting surgeon at the hospital; consultant in orthopedics at the Mercy Hospital-Soniat Memorial; died June 7, aged 75.

David I. Wolfstein, Cincinnati; Medical College of Ohio, Cincinnati, 1888; professor emeritus of psychiatry at the University of Cincinnati College of Medicine, where he had been a member of the board of trustees from 1912 to 1921; formerly professor of pathology at his alma mater; member of the American Neurological Association; served on the staffs of the Cincinnati General and Jewish hospitals, Cincinnati, and the Speer's Memorial Hospital, Dayton, Ky.; instrumental in building the new Cincinnati General Hospital; active in the establishment of the modern board of health and in the campaign for pure milk; in 1898 received the Fiske Fund prize for his essay on "Relation of the Neuron Theory to Diseases of the Nervous System"; a member of the House of Delegates of the American Medical Association in 1905; formerly president of the City Club; died June 7, aged 82, of congestive cardiac failure and arterial disease.

Herman Sinclair Judd, Fort Steilacoom, Wash.; Rush Medical College, Chicago, 1895; member of the Washington State Medical Association; served in the medical corps of the U. S. Army during World War I; at one time surgeon for the Homestake Mining Company at Lead, S. D.; served for five years with the U. S. Veterans Bureau, for a time with the Cushman Hospital, Tacoma, and as acting clinical director of the U. S. Veterans Hospital, Palo Alto, Calif.; formerly city director of health of Tacoma and superintendent of the Tacoma Contagious Hospital; for three months relieved the health commissioner of Alaska; in 1933 appointed surgeon in the Indian Service, U. S. Department of Interior, Prince of Wales Island, Alaska; since 1934 on the staff of the Western State Hospital, where he had been on the staff from 1919 to 1921; died April 19, aged 71, following a prostatectomy.

Jacob F. Burkholder * Chicago; Western University Faculty of Medicine, London, Ont., Canada, 1892; formerly president, professor and head of the department of anatomy, and professor of biology and ophthalmology, Reliance Medical College; at one time president and treasurer, board of directors, professor and head of the department of anatomy, Illinois Medical College; served as junior dean, professor of ophthalmology

and head of the department at Bennett Medical College of Chicago, Medical Department of Loyola University; formerly professor of anatomy at the Chicago Eye, Ear, Nose and Throat College and professor of physiology in the University of Illinois College of Dentistry; author of "Anatomy of the Brain"; died June 7, aged 82, of myocarditis with dilatation.

Hugh Jameson * Titusville, Pa.; University of Edinburgh Faculty of Medicine, Edinburgh, Scotland, 1889; fellow of the American College of Surgeons; examiner for the draft board during World War I; served as member and for many years president of the board of health; a member of the City Council and a member of the school board; a member of the surgical staff and for many years president of the Titusville Hospital; served as a director of the Y. M. C. A. and the chamber of commerce; a member and past president of the Rotary Club; since 1924 surgeon for the Pennsylvania Railroad; died April 20, aged 77, of chronic valvular heart disease.

William Kress McIntyre * St. Louis; St. Louis University school of Medicine, 1923; specialist certified by the American Board of Surgery; member of the American Proctologic Society and fellow of the American College of Surgeons; assistant in surgery at his alma mater from 1928 to 1938, when he became instructor and since 1941 had been senior instructor in surgery; assistant surgeon, St. Mary's Group of Hospitals, and St. Anthony's Hospital; on the surgical staff, De Paul Hospital; proctologist, Isolation Hospital, City Sanitarium and City Infirmary; proctologist, St. Louis County Infirmary, Clayton; died April 29, aged 47, of lymphosarcoma.

August Edward Witzel, Newark, N. Y.; Syracuse University College of Medicine, 1916; member of the Medical Society of the State of New York; fellow of the American Psychiatric Association; formerly senior assistant physician at the Utica State Hospital, Utica; served as director of clinical psychiatry and assistant physician at the Brooklyn State Hospital; on July 1, 1940 became acting medical inspector for the state department of mental hygiene and held that post until Oct. 1, 1940, when he was appointed medical superintendent of the Newark State School; died May 15, aged 53, of coronary thrombosis.

Arthur A. Stevens * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1886; formerly professor of applied therapeutics at his alma mater and professor of materia medica, therapeutics and clinical medicine at the Woman's Medical College of Pennsylvania; served on the staffs of the Episcopal, Philadelphia General and St. Agnes hospitals; author of "A Text-Book of Therapeutics," "A Manual of the Practice of Medicine" and "The Practice of Medicine"; co-author with Florence A. Ambler of "A Textbook of Medical Diseases for Nurses"; died June 10, aged 79, of coronary thrombosis.

William Daniel Snively * Rock Island, Ill.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; past president of the Rock Island County Medical Society; served as treasurer of the Illinois-Iowa Central District Medical Association; examiner for the draft board during World War I and II; a member of the staff, and for many years instructor of obstetrics in the school for nurses, St. Anthony's Hospital; on the staffs of the Public Hospital and the Lutheran Hospital, Moline, where he died April 5, aged 71, of carcinoma of the stomach.

C. A. Barron, Kingsland, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; died April 24, aged 57, of heart disease.

George William Belting, Orfordville, Wis.; Northwestern University Medical School, Chicago, 1909; member of the State Medical Society of Wisconsin; past president of the Rock County Medical Society; died April 17, aged 65, of cerebral hemorrhage.

Walter Griswold Bisbee, Bristow, Okla.; Dartmouth Medical School, Hanover, N. H., 1901; member of the Oklahoma State Medical Association; served as secretary of the Creek County Medical Society; a captain in the medical corps of the U. S. Army during World War I; on the staff of the Cowart-Sisler Hospital; a member of the Rotary Club; died March 17, aged 67, of angina pectoris.

Joseph F. Bowen, Rushville, Ind.; Medical College of Indiana, Indianapolis, 1897; member of the Indiana State Medical Association; past president of the Rush County Medical Society; on the staff of the Henry County Hospital, New Castle, and formerly on the staff of the City Hospital; died April 21, aged 73, of cerebral hemorrhage.

George Thomas Brinkley * Whiteville, Tenn.; Memphis Hospital Medical College, 1902; past president of the Fayette-Hardeman Counties Medical Society; city health officer; a director of the Whiteville Savings Bank; died April 10, aged 68, of coronary occlusion.

George Newton Bussey • Chicago; Rush Medical College, Chicago, 1893; fellow of the American College of Surgeons; co-founder and on the staff of the Ravenswood Hospital, where he died May 1, aged 78, of myocardial failure, chronic arteriosclerotic myocarditis and chronic pyelonephritis.

George Beresford Caulfield, Bangor, Maine; Tufts College Medical School, Boston, 1898; died April 4, aged 79, of heart disease.

Leon Cherurg, New York; University of Dorpat Faculty of Medicine, Russia, 1884; Eclectic Medical College of the City of New York, 1889; died in the Columbus Hospital April 18, aged 82, of arteriosclerotic heart disease and decompensation.

Albert Briton Clark, Swartz Creek, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1889; served during World War I; formerly affiliated with the Hurley and St. Joseph hospitals, Flint; died April 17, aged 78, of carcinoma.

Mildred Naomi Johnson Clark, Omaha; University of Nebraska College of Medicine, Omaha, 1925; clinical assistant in obstetrics at her alma mater; on the staffs of the Bishop Clarkson Memorial and the University of Nebraska hospitals; in 1938 president of the Omaha chapter of the American Medical Women's Association; for many years physician for the Juvenile Court; physician for the Maternal Health League and trustee of the Nebraska Crippled Children's Society; died April 3, aged 44, of coronary thrombosis.

John Gerard De Bey • Orange City, Iowa; Drake University College of Medicine, Des Moines, 1910; died April 17, aged 60, of heart disease.

Robert Edward De Witt, Abilene, Texas; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899; member of the State Medical Association of Texas, served as director of the Delta County Health Unit; for a short period assistant superintendent of the Austin State School, Austin; since October 1943 director of the Abilene-Taylor County Health Unit; died April 2, aged 64, of coronary occlusion.

Benjamin Matthew Domser • Syracuse, N. Y.; Syracuse University College of Medicine, 1910; on the staffs of the Hospital of the Good Shepherd, Syracuse University and St. Mary's Maternity Hospital; died April 26, aged 67, of cerebral hemorrhage.

John Adams Drake Jr., Monroe, Va., Medical College of Virginia, Richmond, 1903; died in the Lynchburg General Hospital, Lynchburg, April 14, aged 62, of bronchopneumonia and carcinoma of the larynx with pulmonary metastasis.

Robert J. Ferguson, New Haven, Conn.; Hahnemann Medical College and Hospital of Philadelphia, 1899; member of the Connecticut State Medical Society and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; a member of the consulting staff at Grace Hospital; died in the Flower and Fifth Avenue Hospital, New York, May 15, aged 72, of carcinoma of the cecum with metastasis.

David Henry Galloway, Roswell, N. M.; College of Physicians and Surgeons of Chicago, 1893; on the staff of St. Mary's Hospital; died March 30, aged 85, of chronic myocarditis.

Robert Hunter Garthright, Vinton, Va.; Medical College of Virginia, Richmond, 1885; member of the Medical Society of Virginia; died May 2, aged 86, of cerebral thrombosis.

Edward Francis Gleason, Hyannis, Mass.; University of Vermont College of Medicine, Burlington, 1899; member of the Massachusetts Medical Society; one of the first members of the staff at Cape Cod Hospital; died April 9, aged 75.

Warren Francis Greene, Eric, Pa.; University of Buffalo School of Medicine, 1941; member of the Medical Society of the State of Pennsylvania; diplomate of the National Board of Medical Examiners; first lieutenant in the medical reserve corps, U. S. Army, not on active duty; on the staff of St. Vincent's Hospital, where he died April 24, aged 29, of leukemia.

George Albert Hass, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; served during World War I; died April 16, aged 56, of cerebral thrombosis, arteriosclerosis and cirrhosis of the liver.

Alonzo Albert Holdbrooks, New York; Howard University College of Medicine, Washington, D. C., 1915; died April 19, aged 61, of burns received when his home caught fire.

Albert Clare Holley, Attica, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1896; member of the Indiana State Medical Association; died in the Maris Hospital, Williamsport, April 26, aged 71, of pernicious anemia.

Nehemiah Janko • New York; Baltimore University School of Medicine, 1898; an Affiliate Fellow of the American Medical Association; died April 13, aged 71, of heart disease.

Clyde White Jones, West Blocton, Ala.; University of Alabama School of Medicine, 1912; member of the Medical Association of the State of Alabama; died April 9, aged 55, of acute myocarditis, coronary thrombosis and decompensation.

William Anthony King, Pittsburgh; Temple University School of Medicine, Philadelphia, 1927; member of the Medical Society of the State of Pennsylvania; served on the staff of the Western Pennsylvania Hospital; died April 25, aged 47, of coronary occlusion.

Charles John Laserte • Leominster, Mass.; Baltimore Medical College, 1905; chief of medical staff, Leominster Hospital; died April 14, aged 63, of coronary thrombosis.

Michael William Lash • Detroit; Wayne University College of Medicine, Detroit, 1938; served a residency in urology at the Cherk Hospital and one in surgery at the Providence Hospital, where he died April 8, aged 30, of virus bronchopneumonia.

William Joseph Powers, Holyoke, Mass.; Baltimore Medical College, 1902; died February 6, aged 64.

Benjamin Spottswood Preston, Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1902; also a pharmacist; member of the West Virginia State Medical Association; served as medical director for the Hillcrest Sanatorium; formerly chief of staff of the Charleston General Hospital; member of the Rotary Club; died at Lewisburg, April 19, aged 70, of cerebral hemorrhage.

Henry James Profant • Santa Barbara, Calif.; Rush Medical College, Chicago, 1920; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; member of the staffs of the Santa Barbara Cottage, Santa Barbara General and St. Francis hospitals; died April 29, aged 51, of ruptured left ventricle.

Marion Roman Siudzinski, • Brooklyn; Long Island College Hospital, Brooklyn, 1914; served during World War I; assistant roentgenologist on the staff of St. Catherine's Hospital; died May 6, aged 53, of cerebral hemorrhage.

Charles D. Stratton • Rotllville, Mo.; Missouri Medical College, St. Louis, 1883; past president of the Chariton County Medical Society; died April 5, aged 85, of bronchopneumonia.

Arthur Deming Whiting, St. Cloud, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1895; died March 19, aged 71, of coronary thrombosis due to hypertension.

Dayton Henry Clinton Wilson, Philadelphia; Temple University School of Medicine, Philadelphia, 1921; died in the Graduate Hospital March 20, aged 52, of myocardial failure, hypertension and cardiorenal disease.

KILLED IN ACTION

Edward Draper Curtin, San Bernardino, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1941; served an internship at the Los Angeles County Hospital, Los Angeles; prior to the time when he was commissioned in the U. S. Navy he served as surgeon in the Douglas Aircraft Company in Iran, where he was stationed for fifteen months, and later in Eritrea; lieutenant (jg), medical corps, U. S. Naval Reserve; awarded Purple Heart posthumously on April 24; died in the Pacific area March 27, aged 28, of multiple wounds.

LIEUT. (JG) EDWARD D. CURTIN,
(MC), U.S.N.R., 1915-1944

Correspondence

PRESCRIPTION WRITING

To the Editor:—The significance of Dr. Kretschmer's article (*THE JOURNAL*, June 3, p. 326) will be obvious to many physicians.

In my book on Pharmacology and Therapeutics I wrote: For three obvious reasons the writing of prescriptions is the dread of the young medical practitioner. These reasons are (1) fear that he may not express his desires correctly, (2) distrust in his ability to make satisfactory combinations or palatable mixtures, (3) anxiety lest a faulty construction should make him the subject of the pharmacist's criticisms.

If a physician cannot write, or is afraid to write, for what he wants he has no recourse but ready made formulas.

Four classes of teachers might be called on to teach prescription writing: pharmacologists, clinical teachers, pharmacists and physicians who have graduated in pharmacy.

Pharmacologists: As Dr. Kretschmer ascertained, of the teachers of pharmacology responsible for teaching prescription writing 58 of 146 do not hold a medical degree, and of the 88 who are M.D.'s only 43 have practiced medicine. How can these appreciate the importance of simplicity combined with correctness in constructing prescriptions to the doctor who sees many patients a day and whose livelihood depends on his success in treating them? Besides pharmacology, prescription writing involves a knowledge of flavors, vehicles and ointment bases, and to a research pharmacologist these are boring details. These might say that teaching prescriptions is something thrust upon them. There is no glory or intellectual stimulation in teaching prescription writing.

Clinical Teachers: As Dr. Kretschmer intimates, these give no time to intensive study of treatment. How often the hospital therapeutics is left largely to the interns! There is certainly no effort made by clinical teachers to teach the student how to write prescriptions, perhaps at times because they have little confidence in their own prescription writing technique.

Pharmacist Teachers: These invariably, I find, recommend complex mixtures for everything, whereas what should be taught the student is the simplest way of prescribing for what he wants. If, of any given drug, capsules or tablets are satisfactory, there is no need to learn how to make up this drug in a liquid form with added syrups, elixirs or flavored solvents. Pharmacists also dwell on incompatibilities, which are really matters of minor import.

Pharmacist Physicians: In my experience the one who writes the best prescription is the man who has graduated in pharmacy and is now a practicing physician.

It would seem as if prescription writing should be taught only when the student is learning clinical medicine and therapeutics, and that means the third or fourth year of his medical course. If taught in the pharmacology course the student does not perceive its practical value, and he is still several years from practicing medicine. Thus, as he passes through the hands of his clinical teachers and subsequently in the hospital prescribes by the use of formulary numbers, he may readily unlearn what he has been taught.

The answer is that the American Medical Association must publish a brochure on prescription writing, not full of rules but merely listing each drug and showing how to prescribe it. It could well be a companion to *Useful Drugs* and might be used not merely by the practitioner but also in the courses on prescription writing.

At a meeting of the deans of a certain noted university, the medical dean, who had abolished the department of therapeutics, was asked "If you do not teach therapeutics in your school how are your graduates going to prescribe for sick people?" He replied "Oh, they pick that up in a year or two." The inquirer

said "Yes, they pick it up from the detail men." In my consultations in towns adjoining New York a common query of the local physician is "Why don't you teach more therapeutics in your medical school?"

NOTE.—The first illustration by Dr. Kretschmer is unfortunate. I should say that a powerful remedy like tincture of nux vomica should never be prescribed by itself. It involves the use of "drops" as dosage, and these vary greatly in size and should not be employed as a dose measure. I saw a woman with typical strychnine poisoning brought on by two or three doses from a bottle of tincture of nux vomica which had become concentrated because the cork had fallen out.

WALTER A. BASTEDO, M.D., New York.

"THE TEACHING OF DRUG THERAPY"

To the Editor:—The article by Dr. H. L. Kretschmer on "The Teaching of Drug Therapy" (*THE JOURNAL*, June 3, p. 326) calls attention again to the fact that the old problem of teaching prescription writing is by no means settled. Of course it is true that pharmacology is the basis for therapeutics, but pharmacology may also be applied to the diagnosis and prevention of disease as well as to the cure of disease and the alleviation of the symptoms of disease.

Pharmacology as a science is the study of the action of chemicals on living things. It is largely a matter of tradition that prescription writing is taught as part of the course in pharmacology. This is unfortunate in many ways. It puts the teacher of pharmacology to a considerable disadvantage, since he rarely has the opportunity for supervising practice in prescription writing on patients.

It would seem that the principles of prescription writing might be taught didactically as part of pharmacology, with practice prescriptions offered regularly through the course in pharmacology in connection with the drugs being studied. Actual practice in prescription writing, however, would seem to be properly a part of clinical medicine. The place to learn how to write prescriptions is at the bedside of the patient under the guidance of a competent clinician.

It is imperative that during instruction in pharmacology full opportunity be taken to acquaint the student with the purposes of the Pharmacopoeia and the objectives of the Council on Pharmacy and Chemistry of the American Medical Association, so as to reduce to a minimum the exploitation of the physician's ignorance of drugs by detail men and pharmaceutical houses. On the other hand, it is equally necessary that clinicians maintain a scientific interest in drugs and that they attempt to use them in a scientific manner. It is wise for clinical instructors to use the United States Pharmacopoeia and the National Formulary as well as New and Nonofficial Remedies in connection with their teaching efforts in therapeutics. It is also wise for the teaching hospital to devise a guide to prescription writing and an index of "useful drugs." This index might be utilized as an inventory for the drug room of the hospital. If a competent hospital committee should prepare such a hospital formulary, it might result in keeping out of the hospital wards unsatisfactory proprietary drugs. Such a formulary might also help the clinical staff to give effective teaching in practical prescription writing.

It is the responsibility of the pharmacologist to teach how chemicals act on living things and how this knowledge may be utilized in medicine. It is also the responsibility of the pharmacologist to give instruction in the kind of drugs to use and how to prescribe them. However, it is the responsibility of the clinician to supervise practical training in prescription writing.

CHAUNCEY D. LEAKE, PH.D., Galveston, Texas.
Dean, University of Texas School of Medicine.

MEDICAL PARASITOLOGY AND
AND ZOOLOGY

To the Editor:—The recent review of my textbook *Medical Parasitology and Zoology* in *THE JOURNAL*, April 8, page 1091, challenges a reply. In paragraph 3 the completeness of the glossary is questioned by the reviewer, who evidently overlooked the needs of the student for such aid in an elementary textbook of this subject. For a similar reason subdivision of the bibliography into that derived from the text and that available generally was deemed quite desirable and helpful to users of the volume.

The allegations of "inaccuracies or inconsistencies of thought or statement" in paragraph 4 of the review are misleading: 1. Craig (1934, p. 132) in describing amebic dysentery mentions repeatedly the presence of blood and mucus in the stools of patients. On page 25 of my textbook I have referred to this condition as a "bloody mucoid diarrhea" for sake of brevity in order to emphasize the contrast between this and the more inclusive condition implied by the term amebiasis. 2 and 3. Chiniofon, anayodin and yatren are not considered as different agents, as the context plainly shows: "It (emetine) should be followed by amebicidal drugs such as the halogen quinoline derivatives—chiniofon, anayodin, yatren, and vioform or carbarsone (an arsenical)." Criticism of the manner in which the administration of these drugs is expressed seems almost too trivial to be worthy of notice. 4. Diodoquin, it is true, should have been mentioned, although it has not yet been widely accepted. Emetine bismuth iodide, however, had been for some years a popular amebicide in Great Britain, but its merits have not been so well recognized here. 5 and 6. Surely the reviewer does not mean to ignore the probable role of exinfestation in transmission of *Enterobius vermicularis* as correctly depicted in figure 31 (p. 139) nor object seriously to classifying *Echinococcus granulosus* and *Hymenolepis nana* as food infesting worms (pp. 201, 206; figs. 54, 56). In case of *E. granulosus* the reviewer evidently would overlook entirely the importance of certain domestic animals in perpetuating and transmitting this species. Associations of the common roundworms in general with soil pollution and flatworms with food infestations or infection is sufficiently accurate to justify their employment pedagogically. Since the life cycle constitutes a basic groundwork for each parasitic worm studied, introducing the idea of environmental relationships at the beginning has distinct advantages. Such a method coordinated with analogous groupings and simplifications in descriptions has been found to assist the student greatly in comprehending the essential features of the principal worms considered. These points seem to be overlooked by most authors of textbooks on parasitology. 7. Sporadic typhus, as described by Brill, has generally been considered murine in origin, although opinions differ as to its exact etiologic relationships.

Now regarding paragraphs 5, 6 and 7 of this review, the critic adds more unimportant remarks and indulges somewhat in generalities. In paragraph 5 he frowns on use of the title *Taenias saginata* and *solium* as a caption covering a brief, combined discussion of these closely related flatworms; he objects to the use of the umlaut u in *Wüchereria*, although it is so employed in various editions of Manson's *Tropical Diseases*; he condemns in one statement part III on arthropods and disease without citing one specific instance. He does pause long enough, however, to praise the new color plate (fig. 22) on malaria parasites.

In paragraph 8 the reviewer admits the unquestioned value of *Medical Parasitology and Zoology* but at the same time offers the dubious advice of supplying the student with a series of mimeographed sheets pointing out the more "serious" errors.

RALPH W. NAUSS, M.D., DR.P.H., New York.

[The letter was sent to the reviewer, who replies:]

To the Editor:—I do not believe that it will be helpful or necessary to consider item by item the points which Dr. Nauss refers to in his letter. I checked all of the points carefully before writing the review and then revised so that there could be no possibility of error in statements included in the review. One of the unfortunate tendencies today in medical writing, perhaps borrowed from newspapers which print only partial truths, is to consider that numerous minor inaccuracies are of little or no consequence. I believe the medical writer owes his physician-reader and medical student the most accurate information available, also the most up to date information. It is on the basis of this thesis that my review was written.

Although I did not make specific statements to this effect, I was much concerned about the recommendations which Dr. Nauss made on the treatment of certain infections considered, since I recognized that he was leaning heavily on Manson-Bahr and was not keeping up with the best American trends. Likewise I did not specifically criticize the numerous diagrammatic illustrations borrowed from Dr. Pedro Kouri, although in 2 or 3 instances I referred to their inaccuracies. A pictorial diagram is one of the best methods of presenting a life cycle of a pathogen and its epidemiology. By the same token, as the diagram is inaccurate the information presented is considerably more damaging than if it had been presented in words.

I realize that Dr. Nauss was sincere in his attempt to provide a useful textbook for medical students. I know that he spent several years in getting the material together. During this period some of the points which I criticized were modified by new knowledge. In other instances Dr. Nauss had failed to understand the need for accurate nomenclature.

INTRAUTERINE PASTES

To the Editor:—The article by Dr. R. W. Weilerstein in *THE JOURNAL*, May 20, reminds me of a fatal case that occurred forty-eight hours after the intrauterine application of an "interruptin" paste containing iodine and fatty substances. I had the chance to perform the medicolegal autopsy of this case together with Dr. Karl Reuter in Breslau (Germany) on July 29, 1931. A brief account of the findings is given by Reuter in the *Medizinische Klinik* 28:1339 (Sept. 23) 1932. The intrauterine application of the paste was made by a physician for interruption of an early pregnancy in a woman 25 years old who had threatened to commit suicide in a stage of reactive depression. The ovum with the placenta was expelled but then a severe dyspnea developed which made the transfer to a general hospital necessary. She died forty-eight hours after the "treatment" had started, with the signs of edema of the lungs. The gross necropsy findings were not striking. There were a few subconjunctival and subendocardial ecchymoses and a severe edema of both lungs. The lungs were heavy, the weight of the left 670 Gm. and of the right 700 Gm. The uterus contained a number of blood clots but no remnants of fetal tissue, and the endometrium did not show any signs of necrosis. In the right ovary there was a corpus luteum verum graviditatis. The microscopic examination revealed as the cause of death an extensive fat embolism of the lungs. All capillaries of the lungs were filled with fat emboli, causing obstruction of the pulmonary circulation. The fat had even passed into the general circulation, where fat emboli were found in all organs, especially the liver, kidneys, thyroid and brain. This fact was interesting because the foramen ovale was closed. The paste had dissolved in the uterus and the fat had penetrated into the uterine capillaries and veins, where it was found at the microscopic examination of the uterus wall; then it had passed into the right heart, the pulmonary arteries and capillaries, obstructing their lumen.

GEORGE STRASSMANN, M.D., Waltham, Mass.
Pathologist, Metropolitan State Hospital.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL*, June 24, page 593.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various centers, Oct. 16. Candidates in military service may take examination at their place of duty. Final date for filing application is August 15. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 5-7. Sec., Dr. S. Judd Beach, 56 Ivie Road, Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Oral and Written.* Part I. Chicago, Oct. 13-14. New Orleans, Sept. 29-30. New York, Oct. 6-7. San Francisco, Oct. 20-21. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* Chicago, Oct. 4-7. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, Sept. 22. *Oral.* St. Louis, Nov. 8-9, New York, Dec. 15-16. Final date for filing application is Aug. 15. Sec., Dr. C. A. Aldrich, 115½ First Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Part I. Various centers, October 25. Final date for filing application is August 15. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Necessity for Expert Testimony as to Physicians' Alleged Negligence.—Hull was seriously injured Sept. 12, 1940 by an explosion in a powder plant that killed over fifty persons and injured many more. He was taken to Dover (New Jersey) Hospital where he was attended by the defendant physician Costello. The defendant physician Plume from time to time took roentgenograms of the patient and on occasion "saw" the patient and consulted with other physicians concerning his condition. On the patient's admission to the hospital the following diagnosis was made: "general lacerations, particularly a severe laceration of the back in the lumbar area, probable injury to spinal cord and nerve system, as evidenced by diminished sensation and paralysis in both legs, shock, and poor general condition, with a very poor prognosis for continuance of life beyond six months." Subsequent diagnosis following the taking of roentgenograms was "fractures of the vertebrae with a displacement of one of the lumbar vertebra, and it showed a foreign body in the boy's back." Apparently, however, there were a number of foreign substances in the patient's body. Dr. Reading, who was called into consultation by the family on Jan. 17, 1941 found that "a prognosis in this case under any circumstances, as far as life is concerned, appears poor." The patient died March 14, 1941, within two days of the six months originally predicted as the probable maximum of life. Subsequently the patient's father, as administrator of his estate, instituted an action against the defendant physicians Costello and Plume, claiming that the death of the patient notwithstanding the serious nature of the injuries received in the explosion was actually caused as the result of the negligent treatment rendered by the defendants. At the conclusion of the evidence presented by the administrator, the trial court directed a verdict in favor of the physicians "because there was no professional or expert testimony upon the question of negligence." The administrator then appealed to the Court of Errors and Appeals of New Jersey.

The crucial question in this case, said the court, is whether the defendant physicians were negligent in the treatment administered, and, if negligent at all, whether such negligence had any causal relation to the patient's death. The administrator contended that while as a general rule those questions could only be determined on the basis of the testimony of medical expert witnesses "where the acts of the defendant physicians are so manifestly and clearly negligent and improper that they can be

recognized as such by the ordinary layman, no expert medical testimony is required." The court, however, did not believe that that exception to the general rule was applicable to the present case. The alleged negligence of the physicians, according to the administrator, consisted of

leaving a large piece of metal in a soiled contused wound for four months and then removing it, and in failing to remove soiled and infectious tissue from the edge of a wound of the size and appearance of the one in question; and in failing to investigate or remedy the presence of urine in an open wound, the same being infectious, the transfusion of blood on only six occasions in four months, on only nine occasions in six months when the treatment required was repeated transfusions, and that infection of the blood stream was permitted to develop.

The testimony, said the court, in this case discloses that the defendant physicians were handling a serious and complicated case of multiple injuries. The patient was in extreme shock, resistance was low, bodily strength was at an ebb most of the time, disturbance by operation or manipulation a risky procedure, and the extreme severity of the initial injuries from the beginning was such that physicians recognized ultimate recovery as probably hopeless and that life itself could scarcely last beyond a few months. In a state of facts of this character, we believe that it was not within the province of any jury to adjudge the validity of the judgment and action of the attending physicians as to the course of their treatment without at least the aid of experts qualified as to knowledge in a field outside the knowledge and experience of laymen, and informed of the actual circumstances of the case in question on which they might deliver their opinion on the basis of either their actual knowledge or assumed facts in a hypothetical question based on the testimony in the case. The court accordingly concluded that the ruling of the trial court as to the necessity for expert testimony was correct.

The administrator contended, however, that if expert testimony as to the negligence of the defendant physicians is essential he had been deprived of an opportunity to present such testimony by the action of the trial court in refusing to permit him to propound questions to Dr. Costello, whom the administrator had called as his own witness, the answers to which would have been evidence as to various forms or hypothetical methods of treatment and would have stated the witness's opinion as to such matters. When the administrator, said the appellate court, sought to propound questions to Dr. Costello which called for answers outside the realm of pure fact, that is, what the physician actually saw and did, and endeavored to elicit from him information as to various forms or hypothetical methods of treatment and to obtain directly his own opinion as to such matters, the administrator was then invading the realm of expert knowledge and opinion in attempting to make of the witness not a mere relator of facts but an expert witness on behalf of the plaintiff. Objections were made to questions called for expert response and we believe were correctly sustained. The applicable statute (R. S. 2:97-12, N. J. S. A.) permits the examination of an adverse party as a witness but provides that "except as otherwise provided by law, when any party is called as a witness by the adverse party he shall be subject to the same rules as to examination and cross examination as other witnesses." One of the established rules in this state, continued the court, as to the examination and cross examination of witnesses is that one may not be called and compelled to give expert testimony unless he shall have voluntarily contracted so to do. *Stanton v. Rushmore*, 112 N. J. L. 115, 169 A. 721. There is no authority for excluding the defendant physician in the instant case from the protection of that rule because he is a party to the litigation, nor do we find any intentment of such exclusion in the case just cited.

The judgment of nonsuit was accordingly affirmed.—*Hull v. Plume*, 37 A. (2d) 53 (N. J., 1944).

Society Proceedings

COMING MEETINGS

National Medical Association, St. Louis, Aug. 14-17. Dr. John T. Givens, 1108 Church St., Norfolk, Va., Secretary.
Utah State Medical Association, Salt Lake City, August 24-26. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Study of 127 Cases of Arthritis (With Notes on Gastrointestinal Features) J. A. Turnbull—p 122.

Arthritis and Gastrointestinal Factors.—Turnbull reviews observations on 127 patients with arthritis, of whom 98 were women and 29 were men. He evaluates the length of time they had suffered from arthritis, age at which arthritis was first manifested and occupation in its possible relation to the etiology of arthritis. Arthritis attacks the finger joints most often; the vertebral joints are least often affected, 37 patients were attacked in all joints. Joints protected by clothing do not appear to enjoy special immunity. A joint previously traumatized will be more severely involved in a general arthritis. A family history of arthritis was obtained in 29.1 per cent of the cases. Etiologic factors of arthritis suggested by this study are food allergy, focal and systemic infection, constipation, gastrointestinal disturbances, trauma, nervous shock, fatigue and exposure. Allied diseases known to be due to protein anaphylaxis are considered in their relation to the occurrence of arthritis. The popular connection between wet weather and arthritis is possibly due to observation of the effects of circulatory disturbances. The cutaneous tests for protein sensitization permit the selection of a diet which in most cases will relieve an arthritic patient of all or the greater part of his symptoms. This therapy is so simple and so readily carried out, requiring nothing more than a little self denial on the patient's part, that it deserves a trial in every case presenting arthritic symptoms.

Louse Control in Civilian Population.—Davis and his associates describe the use of louse killing agents on civilian population in Mexico. The ultimate purpose of the work was to control typhus fever; the immediate aim was to rid an entire

town of lice cheaply, rapidly and with a minimum of equipment. The materials used were a lotion which kills both lice and nits in the hair and powders developed to kill lice in the clothes. The program included these steps: obtaining the cooperation of the people to be treated, mapping of every house in the town, taking a complete census of the town, examining the head and clothing of every person, giving two treatments in successive weeks and evaluating the results a month later. The program was developed in five small Mexican villages. In one of these typhus was epidemic and 64 per cent of the population had body lice. Following treatment, the epidemic stopped and the number of persons with lice approached zero in the second week. A month after the beginning of treatment, only 7 per cent of the population had lice.

Pelvic Reactions to Infections.—Barrett and Lash review observations on 493 patients with partially arrested pelvic infections who were operated on at the Cook County Hospital Clinic. Most reactions to infections overcame the infection, but the reactions left adhesions, thickened tissues, masses large and small, which produced pain and interfered with the function of organs, and were often the site of returning activity by reason of dormant foci or reinfections, so that, in the interest of health, operation became necessary. The etiologic factors were gonococci, abortions and the puerperium. Nulliparas predominated, and 78.7 per cent of the women were below 30 years of age. Surgical treatment was considered only when infection had produced permanent changes in the pelvic structures. In the choice of operation there was a distinct leaning toward conservatism. The important steps in surgical treatment are proper preparation of the patient, proper election of time of operation and rational conservation of tissue. Though gonococci may be common primary and secondary invaders, pyogenic organisms assume the chief role in destroying the female pelvic organs. In these conditions methods of treatment other than surgical are at best only palliative. As the pyogenic organisms, especially streptococci, are commonly found in the tissues, due time must elapse between the last acute exacerbation and the operation to allow immunization of the patient. Though the dormant bacteria were found to be virulent, they were avirulent in the presence of the active antibodies of the patient. The best guides for determining the proper time to operate are temperature, leukocyte curve and the degree of tenderness in the lower part of the abdomen. The foregoing principles were adhered to in the described series of patients and the mortality was only 1.42 per cent, which corresponds to the mortality reported in the literature. The low mortality was largely due to their method of dealing with conglomerated masses, which they outline in this paper.

Topical Application of Horse Serum in Burns.—Rabinowitz and Peltner say that for nearly fifteen years they have employed topical application of normal horse serum to severe burns. They had deduced that local application of horse serum tended to act as a physiologic plug to excessive plasma loss in addition to the healing and bactericidal properties of serum and plasma. After treatment of the burn shock with transfusions, the readily accessible blebs are broken with sterile scissors. The burn is not washed unless it is grossly contaminated, and no débridement is done. The burn is sprayed with normal horse serum, at first every hour and later at longer intervals. A small heat lamp is played over the area until the serum and plasma are coagulated. After about ten days to two weeks the burned part is soaked in sterile saline solution and, as the eschar separates, spraying and saline washings are repeated until complete epithelization takes place. Fifty-two patients with burns of second and third degree were treated in this manner. Eight patients in whom more than 75 per cent of the body surface was involved died within a few hours. In the recoveries the rate and extent of healing seemed remarkably fast. The absence of infection and pain was noteworthy. The healed burns exhibited little or no scarring, and contractures commonly due to burns were not in evidence. In only 1 case was there evidence of mild serum sickness. No skin grafting had to be done on any of these patients. Comparative experiments on animals likewise proved the superiority of the horse serum treatment over treatment with tannic acid and silver nitrate. The authors discuss the role of the protein degradation products cystine, cysteine and methionine in the process of plasma coagulation in burned areas.

Gangrene of Finger Following Digital Nerve Block.—O'Neil and Byrne point out that gangrene occasionally follows digital nerve block. They report 8 cases to illustrate that this complication is not so infrequent as the perusal of the literature would indicate. The injected solution may interfere with the digital circulation and produce gangrene if too much solution is used, if epinephrine is present in the solution or if tourniquets are used. If damage to the circulation is not sufficient in itself to produce the gangrene, subsequent soaking of the finger in hot or even warm water may hasten devitalization of the tissue. Digital nerve block should be replaced, whenever possible, by general anesthesia consisting of pentothal, gas-oxygen or ether. If it becomes necessary to use a local anesthetic great care should be taken in performing the nerve block. No tourniquet nor solution containing epinephrine should be used. Only a small quantity of solution should be used, from about 1 to 1.5 cc. for the entire block. Soaks are contraindicated for at least twenty-four hours.

Feeding Habits of Mosquito Vectors of Encephalitis.—Reeves and Hammon state that as part of an epidemiologic study of the mosquito vectors of encephalitis in the Yakima Valley, Washington, a large series of blood engorged specimens, collected in domestic habitats, were tested by means of the precipitin method to determine the relative proportions which fed on domestic animal reservoirs of these infections and on man. Hand collections were made on the horse, cow and man to determine which of the various mosquito species fed on these

hosts. It was found that *Culex tarsalis*, the species best fitting the epidemiologic picture as a mosquito vector of encephalitis in the Yakima Valley, fed frequently on domestic fowl and included most of the common domestic animals and man in its feeding range. The feeding habits of this species alone could result in the incidence of encephalitis antibodies demonstrated in domestic animals and man in the Yakima Valley. The results of the precipitin tests, and the repeated isolations of virus from *Culex tarsalis*, give strong support to the probability that domestic fowl are an important reservoir of infection in the Yakima Valley.

Dermatitis Venenata and Keratoconjunctivitis Caused by Manzanillo Tree.—Snow and Harley direct attention to the lesions of the skin and eye produced by contact with the lesions of the skin and eye produced by contact with the manzanillo or beach apple tree, which is found along the beaches throughout the Caribbean area and resembles the North American crabapple. During the past two years 18 patients with manzanillo dermatitis have been admitted to Gorgas Hospital. The clinical appearance was similar to that produced by *Rhus toxicodendron*. The patients could recall recent contact with the tree when it was described to them. An acute dermatitis of venenata soon appeared over the exposed areas, consisting of bright erythema, edema and vesiculation. Large blisters at least even bullae an inch (2.5 cm.) in diameter were present in the severe eruptions. The areas most frequently involved were the

face, hands, forearms, upper part of the trunk and genitalia. The manzanillo dermatitis responded to bland, soothing therapy. Cool compresses of solution of boric acid to the face gave relief. For the generalized lesions, especially when there was involvement of the genitalia, cool starch and soda tub baths were helpful. Calamine lotion N. F. with 1 per cent phenol and zinc oxide ointment U. S. P. were used freely. The lesions usually cleared in five to ten days. The eyes were involved in 4 cases. These patients were brought into the hospital with both eyes tightly closed, lacrimating profusely and in pain. There were erythema and edema of the eyelids and vesiculation on the delicate skin about the eyes. Blepharospasm was so great that it was almost impossible to force the lids apart until an anesthetic solution had been applied. Fluorescein stain showed that the corneal epithelium was denuded. Treatment of the keratoconjunctivitis was directed toward preventing infection and waiting for the corneas to reepithelize. To relieve pain a 0.5 per cent solution of tetracaine hydrochloride or an ointment containing tetracaine base was effective. When the spasm of the lid muscles was relieved sufficiently to allow the lids to be separated, the conjunctival sacs were irrigated with copious quantities of isotonic solution of sodium chloride. Effective prophylactic measures are (1) prompt immersion in sea water, preferably with the eyes open, and (2) thorough washing of the entire body with soap and water.

Inoculation of Animals with Trichophyton Purpureum.—Reiss inoculated rabbits with cultures of *Trichophyton purpureum* grown on a 4 per cent dextrose agar medium for from two to three weeks at room temperature. Two strains of organisms were used: (a) a granular strain, which was cultured from a patient with chronic onychomycosis, and (b) a fluffy strain, which was isolated from a patient with chronic disseminated dermatophytosis and follicular involvement of the beard as well as invasion of the skin of the feet, buttocks and scalp. The experiments were done on three series of animals: (1) untreated rabbits (control), (2) rabbits exposed to roentgen irradiation of the spleen and (3) castrated rabbits. Castrated rabbits exhibited the greatest response to the infection, whereas rabbits whose spleen had been exposed to roentgen rays showed a less active infection than the castrated animals. One rabbit inoculated with the cutaneous and intracutaneous methods simultaneously showed traces of infection nine months after the last inoculation. All other control rabbits treated with the cutaneous method alone exhibited a spontaneous cure after six to eight weeks. The clinical features of the infection in rabbits resemble those of the infection in human beings. An allergic reaction could not be elicited by intracutaneous injections of trichophytin. Susceptibility to infection with *T. purpureum* is increased by irradiation and by castration. Fungi were not found in direct examinations of hair from the infected areas. In one section of a cutaneous biopsy only one infected hair follicle was found. This behavior of the fungus in animals is comparable with its behavior in human subjects, in whom the fungus is regularly found in the scales and not in the hair.

Effect of Hemoglobin and Related Pigments on Renal Functions.—The effect of hemoglobin and related pigments on renal function has recently attracted interest owing to the frequency with which anuria was observed after the excretion of myoglobin following crush injuries and during methemoglobinuria accompanying blackwater fever. Acidosis appears to be an important factor in the production of renal lesions in these conditions. Bing investigated the effect of acidosis alone, of acidosis combined with action of hemoglobin, methemoglobin and myoglobin on renal function and compared the information obtained through clearance studies with the pathologic lesions found in the kidney of animals injected with these substances. Intravenous infusion of crystalline methemoglobin into dogs rendered acidotic with ammonium chloride is followed by a fall in the effective renal plasma flow, glomerular filtration

rate and the tubular reabsorptive capacity for glucose. The renal lesion in acidotic dogs infused with methemoglobin consists of hydropic degeneration of the proximal convoluted tubules, cellular necroses in the distal segment and plugging of the collecting tubules with hyaline and in some instances with pigmented casts. Dilatation of the collecting tubules and glomerular damage are absent. Infusions of myoglobin and of hemoglobin into acidotic animals and of methemoglobin and hemoglobin into normal animals fail to produce renal failure. The intravenous infusion of lactic acid and of hydrochloric acid produces a rapid fall in clearances caused by the urinary excretion of methemoglobin. Acidosis produced by oral administration of ammonium chloride has no effect on the renal function.

Penicillin in Experimental Murine Typhus.—Penicillin was shown to inhibit the growth of murine typhus rickettsias in the yolk sac of the developing hen's egg. Moragues and his associates administered penicillin in large but nontoxic doses to mice injected with murine typhus rickettsias. The treatment resulted in a reduction in mortality, particularly when the initial dose of rickettsias was relatively small, approaching the minimal lethal dose. No evidence of secondary bacterial infection was obtained by bacteriologic and microscopic studies. It appears, therefore, that the greatly increased survival rate in the treated mice was caused by the action of penicillin on typhus rickettsias. No prediction can be made from these experiments concerning the effect of penicillin on human typhus infection. Since the

human disease is caused by the growth of rickettsias in vascular endothelium, intravenous injection of penicillin would bring the drug into direct contact with the cells containing the organisms. If sufficiently high concentration of the drug can be established in the blood stream in the early stages of the disease, it would seem reasonable to expect a beneficial therapeutic effect. The results suggest that treatment in the early stages of illness may be important and that the duration and intensity of treatment should be somewhat increased over that ordinarily used in bacterial infections.

Motor Nerve Endings in Early Poliomyelitis.—Carey and his associates describe changes that occurred in the muscles of 3 patients with poliomyelitis. All 3 had died as a result of fulminating bulbar poliomyelitis and had paralysis of the intercostals and accessory muscles of respiration. The poliomyelitic muscle changes were studied by the gold method in comparison with muscles from 2 normal controls. Practically complete denervation of the extrafusal muscle fibers at the myoneural junctions of human respiratory muscles (diaphragm, intercostals, sternocleidomastoid and trapezius) occurred within thirty-six hours of the onset of sore throat and elevated temperature in a fulminating case of bulbar poliomyelitis. This anatomic denervation at the myoneural junction was undoubtedly a terminal result of a pathologic change going on during the incubation period. From 36 to 168 hours after the onset of sore throat and elevated temperature microscopic examination pointed to a rapid centripetal extension of the degeneration in the axons originating possibly in the degenerated motor end plates of many nerve trees. The afferent medullated nerves from and efferent nerves to the intrafusal fibers of some sensory muscle spindles appeared to be more resistant to granular degeneration during the early stages of the disease than were the corresponding motor nerves to the extrafusal fibers in the same muscle. The differential effects of the virus of poliomyelitis on sensory muscle spindles and motor end plates may be the anatomic basis within the musculature for the sensory and motor disturbances in voluntary muscles such as pain, tenderness, myotatic reflex rigidity or shortening, asthenia, ataxia due to disturbance of reciprocal innervation, and flaccid paralysis. There was a striking passive hyperemia of the capillaries in some human muscles. Many muscle fibers had a granular and hyaline degeneration which replaced the transverse and longitudinal striations. There was a proliferation of the perivascular reticuloendothelial mesenchyme leading to the differentiation of epithelial-like lipoblasts in human poliomyelitic muscle. These changes were highly irregular with regard to localization and distribution, so that large amounts of teased muscle material must be studied.

chyme leading to the differentiation of epithelial-like lipoblasts in human poliomyelitic muscle. These changes were highly irregular with regard to localization and distribution, so that large amounts of teased muscle material must be studied.

Prolonged Disturbances of Consciousness Following Head Injury.—The material presented by Moore and Ruesch consists of data obtained from medical, neurologic and psychologic examinations of 39 patients with disturbances of consciousness, such as coma, semicoma, confusion, delirium, stupor, drowsiness and dysphasia lasting longer than seventy-two hours after injury to the head. A high incidence of altered electroencephalogram, skull fracture, bloody spinal fluid under increased pressure and Babinski sign gave evidence that prolonged mental confusion is associated with severe brain damage. Important changes in vital signs were present in only half the cases and appeared to be independent of the presence and duration of confusion. During the period of hospitalization immediately following injury, intellectual disturbances outnumbered other mental abnormalities. Emotional disorders tended to appear later than the cognitive dysfunctions and persisted longer; they were frequent even in cases of short confusion. Ability to speak returned on an average within the first day. The first response to simple psychologic tests appeared during the second week, before correct orientation in place, situation and time, which returned in that order. Drowsiness and restlessness held no fixed place in the order of recovery and appear to be independent of the course of recovery of intellectual function. Gross intellectual defect persisted for six months in 31 per cent of the patients and was preceded in every case by a period of confusion lasting longer than nineteen days. The duration of disorientation proved to be one of the most reliable and easily obtainable criteria of the seriousness of mental prognosis. The total duration of post-traumatic amnesia is directly related to the period of disorientation and thus has equal value but is available only later and is then a purely subjective quantity.

Rice Diet in Renal and Vascular Disease.—Kempner used a dietary regimen consisting of rice, sugar, fruit and fruit juices supplemented by vitamins and iron during the past four years in patients with acute and chronic glomerulonephritis and hypertensive vascular disease. The diet contains in 2,000 calories from 15 to 25 Gm. of protein, 4 to 6 Gm. of fat, 460 to 470 Gm. of carbohydrate, 0.25 to 0.4 Gm. of sodium and 0.1 to 0.15 Gm. of chloride. The amount of fruit juices given daily is usually 700 to 1,000 cc. The diet proved to be beneficial in the majority of the 140 patients who followed this regimen for periods ranging from four days to thirty months in the hospital and at home. In no instance has the diet proved harmful. Careful medical supervision, including studies of blood and urine chemistry, is essential. The histories of 2 patients, 1 with chronic glomerulonephritis, the other with hypertensive cardiovascular disease, are given to illustrate the effects which a rice-fruit-sugar diet may have on hypertension, heart enlargement, electrocardiographic changes, edema, hypoproteinemia, nonprotein nitrogen, hypercholesterolemia, albuminuria and retinopathy.

Sulfonamides in Acute Hemorrhagic Nephritis.—According to Crumpler acute hemorrhagic nephritis is a common disease of infants and children following measles, scarlet fever, skin infections and particularly streptococcal infections of the upper respiratory tract. The hemolytic streptococcus causes most cases of hemorrhagic nephritis; however, *Streptococcus viridans*, the pneumococcus or the gonococcus may occasionally be the invading organism. The onset is gradual. The symptoms are suppression of urine, elevation of blood pressure, nausea, vomiting, edema, confusion and convulsions. Urinalysis shows albumin, red blood cells, white blood cells, casts and decreased urinary function. There is elevation of the nonprotein nitrogen and the blood urea. Since most cases of acute hemorrhagic nephritis are caused by the hemolytic streptococcus the sulfonamides are indicated in their treatment, along with surgical removal of foci of infection when these exist. Sulfanilamide is probably the drug of choice, since it is less likely to crystallize in the urinary tract. The drug is given in relatively small doses, which should be continued until a complete cure is established. Sulfanilamide should be given before and after surgery to prevent an exacerbation or recurrence of the acute nephritis. The author reviews observations in 17 cases of acute hemorrhagic nephritis which have been treated with sulfonamides in the Park View Hospital and at his office with favorable results. There was no evidence of kidney damage in any case.

Plasma for Filling Pleural Space After Loss of Lung Tissue.—Adams and Thornton show that alteration of the blood, in the resection of various amounts of lung tissue, may be considerable. Factors not encountered in operations on other organs may contribute to this alteration, namely (1) the incision is long and usually divides heavy bellied muscles transversely, (2) vascular adhesions are frequently encountered and (3) the amount of blood within the lung may be considerable. Following these operations both cells and plasma of the circulating blood are lost, part of this being drained away (as much as 600 to 1,200 cc. following lobectomy) or allowed to accumulate in the pleural space (as in pneumonectomy). The postoperative course of a patient would be less complicated if a more nearly normal blood picture was maintained. Since resection of the lung is at present frequently indicated for malignancy, bronchiectasis, lung abscess, and tuberculosis, the factor of blood protein replacement assumes greater importance. To determine the method of choice for replacement of protein loss, the authors investigated in animal experiments not only the various causes of blood plasma protein fall but also the replacement therapy. They found that following resection of lung tissue in dogs blood plasma protein levels were reduced by 33½ per cent. This reduction persists for as long as ten days. The removal of lung tissue, the thoracotomy wound, anesthesia and infection are all contributing factors to the fall in plasma proteins. Replacement therapy consisted in the administration of blood or serum intravenously or serum intrapleurally. Both replacement materials and routes of administration were equally effective when the materials were given in adequate amounts.

Repair of Facial Paralysis with Tantalum Wire.—White suggested the use of tantalum wire for repair of facial paralysis. Schuessler describes the tantalum wire method as used at the Walter Reed General Hospital. The method is simple and effective, and it stabilizes the mouth, the lower end of the nose, and the eyelids, thereby transmitting some elements of expression to the paralyzed side. The operation is performed under local anesthesia. No disability or bed rest is necessary, as no incision is made for the removal of fascia from the thigh. When the wires are in position the patient can sit up and the wires can be tightened to the proper tension, thereby doing away with the amount of sagging in the paralyzed side which occurs when the patient is lying down. There is no swelling or hemorrhage in the tissues of the paralyzed side because of the very slight trauma which is produced by the small caliber of the needle. This method can also be used to hold muscles in balance during the time the nerve is regenerating, and when fully recovered the wires can be removed.

Spinal Anesthesia in Treatment of Hirschsprung's Disease.—Hawksley reports 12 cases of Hirschsprung's disease in only 1 of which improvement did not occur. The colon and rectum are innervated by the two antagonistic halves of the autonomic nervous system, the sympathetic inhibiting colonic movements and initiating closure of the sphincters, the parasympathetic initiating intestinal movements and opening the sphincters. It is reasoned that an imbalance exists between the two halves of the autonomic system with overaction of the sympathetic, and it is suggested that by temporarily paralyzing the offending half the parasympathetic can exercise its function unchecked and that on recovery of the sympathetic the two halves are restored to normal balance. The object is to paralyze the anterior roots up to the fifth thoracic at least. Light nupercaine anesthesia 1:1,500 is used and found to be highly satisfactory. No basal premedication is given, but ephedrine is given intramuscularly just beforehand. The nupercaine, warmed to blood heat, is injected into the space between the second and third lumbar vertebrae with the child sitting up. The child

remains sitting for twenty seconds and is then placed on its back in the reversed Trendelenburg position, i. e. shoulders highest; this ensures that the bulk of the nupercaine will affect the anterior roots and will continue to travel upward. This position is usually maintained for five minutes, or until the child complains of pins and needles in its hands. The table is then tilted, bringing the shoulders downward, thus ensuring that the nupercaine will not continue to ascend. On the basis of observations in 12 cases, the author takes a hopeful view of the effect of spinal anesthesia in Hirschsprung's disease.

Malarial Treatment in Early Neurosyphilis.—According to Lescher and Richards, malarial treatment for the earlier forms of neurosyphilis, before the onset of dementia paralytica, has not been extensively employed in Britain. The fact that there is a mortality rate of from 2 to 10 per cent associated with the malarial treatment of neurosyphilis may be responsible for the lack of enthusiasm. These figures have been estimated from results obtained in patients with dementia paralytica, which is a fatal disease. It was reasonable to suppose that if patients were treated with malarial fever before the onset of dementia paralytica the mortality rate should be much less than the figures quoted. The authors used malarial therapy in 20 cases of neurosyphilis before the onset of dementia paralytica. Care was taken that the patients were well nourished and were not suffering from infective or debilitating disease. Patients with gross infection of the bladder or in whom there was evidence of damage to the cardiovascular, renal or hepatic systems were excluded. The authors employed injection of malarial blood for the transmission of malaria. The highest temperature rarely exceeded 105 F. There was no difficulty in terminating the malarial infection. The patients were examined periodically after leaving the hospital. Further chemical treatment has been given when necessary. After combined malarial and chemical treatment clinical improvement has taken place and has been maintained in 15 cases together with improvement in the condition of the cerebrospinal fluid and in the blood serum reactions. The authors suggest that malarial therapy has a place in the treatment of selected patients with the earlier forms of neurosyphilis and that venereal disease clinics should be affiliated with hospitals where facilities for this treatment are available.

Prognostic Value of Laboratory Investigations in Typhoid.—According to Bhatnagar, laboratory investigations in typhoid are usually employed for the confirmation of clinical diagnosis, either directly by the isolation of the infecting organism from blood, urine or feces, or indirectly by the estimation of antibody production, chiefly Vi and O agglutinins. In military hospitals in India blood cultures in the early stages, agglutinations throughout the course of infection and collection of evidence for the excretion of micro-organisms, even during con-

valescence, comprise the routine procedure. Not only was it thus possible to gain an insight into the struggle between host and parasite, but specific antityphoid serum therapy could also be placed on a more satisfactory basis. Prognostic inferences were drawn from a study of 280 cases of typhoid in which laboratory investigations were carried out throughout the course of infection. The cases were divided into six groups: (1) the simple type, which presents the textbook description of the disease, (2) the ambulatory type, (3) the toxic type, (4) the form with prolonged pyrexia, (5) the embolic type and (6) the relapse type. A close association existed between the prognostic outlook and the results of laboratory investigations. It was found that if Vi antibody was present early in a sufficiently high titer (50 to 250) and this titer was maintained over a number of days the course would most likely be short (simple type). In the embolic type, in which the Vi antibody was either absent or seldom above 10 to 20, improvement was preceded by a rise in Vi titer. The prolonged pyrexia type resolved only when a sustained Vi titer was recorded. In the case of remittent fever, absence of Vi antibody or the lack of an appropriate rise in O agglutinins does not exclude the possibility of typhoid. An abnormal rise in O agglutinins was observed in the toxic type, the titer varying from 2,000 to 20,000. Since a considerable fall in the O titer of serum always preceded recovery, the high rise of O agglutinins must be regarded as pathologic. In the ambulatory type complete rest and noninterference with the rise in temperature appear to be of the greatest importance in the second stage of the disease. Relapses occurred in 6 per cent of the series. Unusual laboratory findings appeared to be associated with the possibility of relapse. An early rise in Vi agglutinins should be expected only in mild cases.

Symptomatic Hemolytic Anemia.—Davis reports 4 cases of symptomatic hemolytic anemia. The underlying pathologic conditions were respectively carcinoma of the tail of the pancreas, reticulosis or Hodgkin's disease (2 cases) and subleukemic myeloid leukemia. Acceptance of the diagnosis of symptomatic hemolytic anemia depends on evidence that the anemia is of hemolytic origin and that its onset was preceded by the underlying primary pathologic condition. The recognition of excessive red cell destruction in patients suffering from neoplastic and allied conditions may present difficulties. The least equivocal of these criteria are the demonstration of excessive excretion of fecal urobilinogen, and in cases in which the hemolysis is intravascular the demonstration of methemalbuminemia or hemoglobinuria. The mechanism of hemolysis is obscure in symptomatic hemolytic anemia and may vary according to the nature of the primary pathologic process, as do also the prognosis and treatment. The author has no knowledge of whether hemolytic anemia has been observed in cases of carcinomatous growths which were subsequently successfully extirpated or in cases of leukemia which proved amenable to radiation therapy. In 1 of the reported cases the hemolytic process subsided following the institution of radiation therapy directed against the underlying condition of reticulosis.

Sliding Graft for Ununited Fracture of Tibia.—Burns and Michaelis state that the sliding graft with metal fixation is not as popular as it deserves to be. The sliding graft has been their standard method and has given satisfactory results

in all but 1 of the 26 consecutive cases in which it has been used since June 1940. The use of the sliding graft is particularly applicable to the tibia, for the size and shape of the bone allow a graft to be cut bulky enough for its purpose, while incision and exposure of the bone presents no difficulties or disadvantages. A long skin incision is made about $\frac{1}{2}$ inch lateral to the anterior border of the tibia. It is curved inward at each end. The periosteum is stripped from the subcutaneous surface, a 5 to 6 inch graft is cut in the bone above the level of the fracture and half that length of bone is removed from the subcutaneous surface below the fracture. The graft can be slid down as far as necessary. When the fracture is near the upper end of the tibia it is necessary to slide the graft from below upward. After the graft has been fitted it is fixed by the insertion of four to six vitallium screws. In no instance was the shortening more than $\frac{3}{4}$ inch. The sliding graft is not suitable for gaps larger than this. In infected cases operation was not done until at least three months after the cessation of discharge. Of the 26 fractures in this series 21 were united in three to four months, 3 at five months and 1 at seven months; 1 failed to unite. The authors conclude that, of the methods of grafting for nonunion of the tibia, sliding inlay, fixed with vitallium screws, is the simplest; and it does not necessitate the borrowing of bone from the other leg.

Absorption and Excretion of Sulfonamides in Children.

—It has been suggested that a drug which is only poorly absorbed from the lumen of the intestine would be more effective than one which is well absorbed, because there would be a higher concentration of the drug in the feces. The medical research council recommended sulfaguanidine and succinylsulfathiazole for the treatment of intestinal infections because only 25 to 50 per cent of the former and about 5 per cent of the latter were stated to be absorbed. Paulley found that sulfapyridine had advantages over sulfaguanidine, suggesting that it is not the concentration of the drug in the intestinal contents but the concentration in the blood which is the important factor. During an outbreak of Sonne dysentery in a children's ward, Stanier and Stapleton attempted to control the epidemic by giving each child a forty-eight hour course of either sulfaguanidine or succinylsulfathiazole. They used the urinary excretion as a means of comparing the various amounts of the different drugs absorbed. They found that approximately equal proportions of sulfathiazole and sulfaguanidine are excreted in the urine after the administration of similar doses of the drugs. Only a small proportion of succinylsulfathiazole is excreted in the urine. The blood levels obtained with sulfathiazole are slightly higher than those obtained with sulfaguanidine; this may be partly because sulfathiazole is excreted slightly more slowly than sulfaguanidine. In the light of these observations it might be expected that succinylsulfathiazole is of most value as a prophylactic against bacillary dysentery, but possibly not to be as effective as either sulfathiazole or sulfaguanidine in the treatment of established cases. When using either sulfathiazole or sulfaguanidine it is important to ensure an adequate urinary output, and with sulfathiazole the urine should be kept alkaline.

Tobacco Smoking and Pulmonary Complications After Operation.—Morton investigated the incidence of bronchitis, atelectasis and bronchopneumonia after abdominal operations and "gas-oxygen-ether" in 1,257 adults. The use of omnopon-scopolamine, a mild respiratory depressant, for premedication was associated with a slight but not significant increase in pulmonary complications, as compared with the use of atropine alone, which has no depressant effect. The combined figures for all types of abdominal operations show that the morbidity rate for smokers taking more than ten cigarettes a day is about

six times that for nonsmokers. Smokers are more likely to develop complications associated with serious constitutional disturbance. The sex incidence ratio of pulmonary complications is explained. When abdominal operations are contemplated, it is advisable for smokers to stop or reduce their smoking as a precaution against pulmonary complications.

Corneal Vascularization in Nutritional Deficiency.—Many students of nutrition regard corneal vascularization as a specific sign of riboflavin deficiency. The relationship between corneal vascularization and nutritional status in Royal Air Force personnel has been investigated in the past two years in twenty-two localities. In some localities the standard of feeding was good, while in others it was less satisfactory either because of lack of local supplies or because importation of some desirable foodstuffs was impossible. Nearly 4,000 subjects have been examined, and at some stations the effects of supplementing the diet have been studied. Many of the men who had excellent diets had blood vessels on the cornea, and subjects with much corneal vascularity did not always improve when the diet was supplemented. Vascularity of the cornea is apparently not necessarily an evidence of deficiency in the diet. On the other hand, there was little corneal vascularity where the food was good and more where food was less satisfactory. The average degree of corneal vascularity in a group of subjects is therefore a reliable index of their general state of nutrition. Riboflavin is not the only nutrient concerned in the prevention of corneal vascularization. These experiments suggest that other factors present in fruits and vegetables influence this condition more than riboflavin.

Necrobacillosis in Man.—According to Forbes and Goligher the term necrobacillosis covers a wide variety of animal diseases due to infection with a gram negative nonsporing filamentous anaerobe. An organism of this description has been recovered from the caseonecrotic lesions of equine bacillary necrosis, calf diphtheria, "foot rot" in sheep and pigs, labial necrosis in rabbits and hepatic necrosis in cattle. In all of these the basic pathologic process is the same: there is a local lesion with a tendency to necrosis, and often metastatic abscesses develop in lungs and liver. The taxonomic position of the causative organism has not been definitely established, and it is known by many names. The authors prefer the term *Bacterium necrophorum*. The organism rarely attacks human beings. Although it has been recovered from the healthy human colon and also from the colon in ulcerative colitis, few cases are on record in which it has been clearly pathogenic to man. The authors report that a man aged 24 sustained an open fracture of the leg and various minor wounds during a naval engagement. After a month the fracture wound was still heavily infected, and signs of septicemia developed. Chemotherapy was ineffective, and the leg was amputated. Aerobic blood culture was negative, but a gram negative filamentous organism resembling *Bact. necrophorum* was isolated from pyemic abscesses and was later grown anaerobically from the blood. On the patient's death, after nearly twelve weeks' illness, multiple pyemic abscesses were found in the lungs and under the skin. The source of infection in the case recorded is a matter for conjecture. At no time during the history of the wound was the patient exposed to an obvious extraneous source of infection. He was on a destroyer at sea when the wound was received.

- *Prophylaxis Against Typhoid, Paratyphoid and Dysentery: Measures to Be Taken with Carriers. R. Regamey.—p. 611.
Doctor's First Aid Kit. E. A. Hafner.—p. 616.
Diagnosis and Therapy of Otitis Media. L. Rüedi.—p. 617.

Measures to Be Taken Against Typhoid Carriers.—Regamey discusses measures to be taken against typhoid carriers with consideration of the conditions existing in Switzerland. He recommends the creation of an office of control of carriers by the cantonal authorities. Two types of carriers are difficult to detect: these are (1) the mildly infected, in whom the disease takes an atypical course and who may not come under the care of a physician, and (2) the healthy carriers without previous symptoms. The author maintains that there is invariably a carrier of germs at the basis of all typhoid, paratyphoid and dysentery cases. Every new infection must be made the object of an investigation until the responsible carrier is detected. The Gruber-Widal reaction gives uncertain results. The search for Vi antibodies in the serum is more fruitful; the author found it particularly useful in the examination of large groups (asylums). There is no treatment that can be recommended to the carrier with certainty of success. The author mentions the use of arsphenamine, vaccines, phages, chemotherapy with sulfonamides, acriflavine hydrochloride, magnesium sulfate, zinc sulfate and others. The parasites may disappear spontaneously. Carriers whose occupation involves contact with foods must change their occupation. If this entails financial loss, the office of control should see to it that suitable indemnity is granted. This office should also punish infractions which endanger public health. Other tasks of the office of control are the education and bacteriologic control of the carrier and the hygienic supervision of persons in the environment of the carrier.

Tumors of Cauda Equina.—Diez discusses the importance of unilateral or bilateral, intractable sciatica for an early diagnosis and early successful operation on tumors of the cauda equina. Pain, as the only symptom, may begin suddenly, disappear for a long time and reappear with a progressive intractable course or it may be progressive and intractable from the beginning. The differential diagnosis of sciatica caused by tumor from rheumatic and arthritic sciatica and sciatica caused by protrusion of the intervertebral disk or by hypertrophy of the ligamentum flavum is made by the chemical examination of the cerebrospinal fluid, by manometric determination and roentgenogram examination of the spine after subarachnoid injection of iodized poppyseed oil.

- *Pulmonary Embolism Complicating Puerperal Thrombophlebitis. R. Dubrovsky and E. A. Linzoain.—p. 64.
Traumatic Rupture of Spleen. C. A. Castro.—p. 66.

Pulmonary Embolism Complicating Puerperal Thrombophlebitis.—Dubrovsky and Linzoain classify pulmonary embolism complicating puerperal thrombophlebitis into (1) hyperacute, (2) acute, (3) subacute and (4) moderate. In treatment of the last three types they employ intravenous injections of papaverine. A solution containing 0.03 Gm. of papaverine hydrochloride per cubic centimeter is slowly injected. From 2 to 7 cc. of this solution is administered to persons with the acute and subacute types and half that dose to persons with the moderate type. An intramuscular injection of from 0.01 to 0.015 Gm. of morphine hydrochloride is administered before or immediately after injection of the papaverine to persons with the acute type and half the dose to persons with the subacute type. These injections can be repeated if necessary.

Book Notices

Medical Physics. Editor-in-Chief: Otto Glasser, Ph.D., Head, Department of Biophysics, Cleveland Clinic Foundation, Cleveland, Buckram. Price, \$18. Pp. 1,744, with illustrations. Chicago: Year Book Publishers, Inc., 1944.

Although some of the earliest investigators in the field of medicine were physicists, physical agents were not used extensively for therapeutic and diagnostic purposes until recently. This volume covers briefly many applications of the physical principles used in various branches of medicine. The book is well illustrated and is carefully edited. Each chapter contains an extensive list of references covering the sources of material for the chapter or giving reference for additional reading matter. The classified table of contents contains sections on anatomy, bacteriology, biometrics, biophysics, dermatology, hematology, medicine, neurology, nuclear physics, ophthalmology, optics, orthopedics, otolaryngology, pathology, pediatrics, photography, physical chemistry, physical therapy, physics (instruments and methods), physiology, radiology, surgery and urology. In each of these categories the part played by physics is considered. Both diagnostic and therapeutic devices are given careful attention, and all applications of physics in medicine are dealt with adequately. One does not have to be a mathematician to derive useful information from the book. Mathematics is used, but the mathematical formulas are accompanied by word descriptions. There are ample diagrams, charts and tables to bring out the importance of the subject matter at hand. In short, the book presents the elements of physics effectively for specialists practicing physical medicine and radiology and serves as an adequate reference handbook for the physician in other fields.

Persistence and Change in Personality Patterns. By Katherine Elliott Roberts and Virginia Van Dyne Fleming. Monographs of the Society for Research in Child Development, Volume VIII, No. 3 (Serial No. 36). Paper. Price, \$1.50. Pp. 206, with 25 illustrations. Washington, D. C.: Society for Research in Child Development, National Research Council, 1943.

This monograph attempts to answer the question "Are human traits fixed, or are they modified by life experiences?" The material dealt with consists of the life histories of 25 women interviewed in the Advisory Service for College Women of the Merrill-Palmer School in Detroit. Part I presents three of these histories (original "average length 90,608 words") in condensed novelette form, but, possibly because the authors themselves did not do the interviewing, the published anamneses show little insight into the nuances of individual and social development of their subjects. Substituted are the usual clichés about "feelings of inferiority," "difficult relationships," "emotional outlets" and other phrases used as secondary evaluations of the original biographic data. From such histories, nevertheless, various "traits" such as "shyness" and "strong ego drive" are then further abstracted, coded, tabulated and analyzed for the factor of "persistence," which admittedly varied from case to case. Despite the methodologic tenuousness of such procedures, the authors then construct tables to show that traits such as "seeks help when needed" rate only 11 per cent persistent, whereas "has a few friends in whom she confides" is 100 per cent constant, presumably up to the time the subject confided in the interviewer. The authors conclude that "there seems to be a nuclear personality pattern for every individual . . . and around this nucleus other traits and attitudes shift as life proceeds . . . even the nuclear pattern may change when conditions are changed radically." To answer the subsidiary question "Do homes matter?" the authors classify their subjects into those from "happy" homes (5) "unhappy" homes (4) and "medium" (16), according to criteria like "gets along with parents" vs. "thinks mother considers doing things for children too much trouble." The authors conclude, again somewhat predictably, that homes matter.

Similar revelations by tabular divination are then related to chapter headings such as "Is Personality Related to Marital Happiness?" "Personality and Religious Values" and "Social Adjustment and Personality." There is a fifty-six page appendix of tabular data without specific or implied qualifications to the effect that these "data" really represent the authors' abstracted opinions of the interviewers' recorded opinions of the

subjects' expressed opinions of themselves. Characteristic also is the inclusion of several elementary textbooks and three dictionaries in the bibliography of twenty-nine titles, with almost no reference to the rich literature of psychoanalytically and clinically oriented studies in the field.

The main defects of this monograph are those of the traditional academic approach to personality: methodologic devotions to questionnaire "tests," the tabulation of "traits" or other vague generalities and the statistical derivation of the same pedantries that were originally injected into the material. Despite the undoubted sincerity of its composition, therefore, this monograph is recommended only as a documentary case study of a rapidly passing preoccupation with the trite and the sterile in our concepts of personality.

The American Illustrated Medical Dictionary: A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, Etc., with the Pronunciation, Derivation, and Definition. By W. A. Newman Dorland, A.M., M.D., F.A.C.S., Lieut.-Colonel, M. R. C., U. S. Army. With the collaboration of E. C. L. Miller, M.D., Medical College of Virginia. Twentieth edition. Fabrikoid. Price, \$7; Thumb indexed, \$7.50. Pp. 1,668, with 885 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This is a complete revision of this dictionary, involving changes on every page. Many hundreds of new words have been added, including all of the new fields at present associated with medicine, such as mycology, and all of the new techniques that have been developed in recent years. Especially important as a feature of this edition is the incorporation of the terminology of the Standard Nomenclature of Diseases and Operations. The definitions in each instance and the descriptions of operations appear under the terms preferred by the Standard Nomenclature. This volume, as is apparent from its preface, represents today an effort in which many of the leading institutions devoted to medical education and medical publication of the United States cooperate. Thus the assistance is recorded of the editorial staff of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the editorial staff of the Mayo Clinic and the staffs of the libraries of the New York Academy of Medicine and of the College of Physicians of Philadelphia. Furthermore, a number of individuals have cooperated by submitting some new terms much used in medicine. The present edition contains almost 1,700 pages, almost a thousand illustrations and great numbers of useful tables, including finally a complete dosage table.

Synopsis of Diseases of the Heart and Arteries. By George R. Herrmann, M.S., M.D., Ph.D., Professor of Medicine, University of Texas, Galveston. Third edition. Fabrikoid. Price, \$5. Pp. 516, with 107 illustrations. St. Louis: C. V. Mosby Company, 1944.

The appearance of a third edition of this excellent synopsis is welcome. The contents have been considerably revised and brought up to date, with emphasis on the problems arising from the war. The order of the chapters has been shifted, and four new chapters have been added on nervous disorders with cardiac manifestations, blood pressure abnormalities, essential hypertension and general systemic types of heart disease. The new arrangement and the new chapters have greatly improved the book. The reader for whom this volume is intended will derive great benefit from its perusal, but the reviewer believes that there is undue repetition of material in several places, the avoidance of which would considerably strengthen the book. It would also permit expansion of the handling of some topics which have been pruned to barrenness, a failing common to all synopses.

The Control of Cross Infection in Hospitals. (Memorandum Prepared for the Committee on Preventive Medicine of the Medical Research Council by the Sub-Committee on Cross Infection in Hospital Wards.) Medical Research Council War Memorandum No. 11. Paper. Price, 15 cents; 6d. Pp. 34, with 6 illustrations. New York: British Information Services. London: His Majesty's Stationery Office, 1944.

The topics discussed are prevalence and consequences of cross infection, sources and modes of infection, the prevention and control of cross infection, and procedure following the occurrence of infection in a ward. Disinfection and sterilization, special rules and precautions, and a course of bacteriology for nurses are described in appendixes. There is a useful list of references. The memorandum will be helpful in the working out of efficient procedures to control cross infection in hospitals.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CONTAMINATION OF BEVERAGES AND FOOD WITH LEAD

To the Editor:—Are there any reports in the literature of lead poisoning from containers in which milk and water are boiled or other foods cooked? What is the present belief regarding the hazards of using pewter as a container for food or drinking water?

Rudolfo Perez de los Reyes, M.D., Havana, Cuba.

ANSWER.—There are many references in medical literature to widely varied sources of contamination with lead of milk and other beverages including water, as well as foods. However, reports of cases of lead poisoning are relatively infrequent and are not always substantiated by acceptable evidence. No doubt the comparative rarity of such cases is due to the fact that these contaminations are usually small, and, except in the case of certain community sources of water supply, are spotty in their occurrence and so do not result in regularly repeated exposures to hazardous dosages. Milk and many other foods take up lead from containers that are soldered on the inside and from utensils coated inside with tin-lead alloys. The use of new skillets coated thinly with tin-lead alloys is a particularly fruitful source of contamination, but their coating of tin (containing lead) tends to be melted off soon, and the remainder becomes coated with a film which reduces the contact with the food. Lead glazed containers also may contaminate food and beverages that have solvent properties. Old pewter of high lead content is generally unsatisfactory as a container for beverages, especially those of high acid content, although here too the surface becomes coated and resists solution to a considerable degree if it is not cleaned frequently with abrasives. Much of the modern pewter has a low or negligible lead content, but unfortunately one cannot always be certain that this is the case.

The important consideration in this entire problem is the regular daily dosage of lead in the food and beverages from all sources. If this is much in excess of 0.5 mg. of lead over any considerable period of time (months) in the case of adults, it constitutes a potential hazard. In the case of children the daily dosage should be limited to a somewhat lower level. Poisoning does not occur in either adults or children from occasional ingestion of considerably larger amounts or from regular ingestion of amounts of the order of magnitude of 0.2 to 0.3 mg. a day in the food and drink.

SULFONAMIDE THERAPY AND WASSERMANN REACTION

To the Editor:—Are the sulfonamides known to cause false positives in the Kahn and Wassermann serologic tests? I have in mind several instances in which positive reactions have occurred in patients receiving sulfonamide treatment, and the positiveness seems more likely due to uncomplementary reaction than to true social diseases. I would appreciate any enlightenment you may have to offer on this point.

William A. Voke, Medical Technologist, Tucson, Ariz.

ANSWER.—The observation that sulfonamide therapy may cause positive serologic reactions for syphilis has not been recorded by others. It is known, however, that anticomplementary reactions may occur during the course of certain infectious diseases, nonsyphilitic in origin. As to the observations in question, one would like to know if tests were carried out just prior to the administration of the sulfonamides, what infectious diseases were being treated and whether the patients were quite afebrile. It is suggested that the foregoing observations should be repeated with a series of suitable control tests; that is, tests performed just prior to sulfonamide therapy, during therapy, and several days after therapy has been discontinued.

REMOVAL OF CLAMP FROM UMBILICAL CORD

To the Editor:—How long after the application of a clamp (e. g. Kone type) to the cord of the newborn can it be safely removed?

M.D., New York.

ANSWER.—It has been demonstrated that no more bleeding occurs from the cord after a clamp has been applied to it for ten minutes. However, cord clamps can be removed safely at the end of twenty-four hours.

WARTS IN CHILDREN

To the Editor:—A young girl has numerous verrucae covering her lips and the inner sides of her cheeks. She has always been in excellent health; she has had none of the childhood diseases except measles. Her Wassermann reaction is negative, blood count within normal limits and urinalysis negative. I am unable to find anything in the books on the diseases of children covering the subject and would appreciate it if you would help me out in suggestions as far as treatment is concerned. The lesions are too numerous to be treated by cautery.

M.D., North Carolina.

ANSWER.—There is no description of the type of warts which this young patient has, but if these are the usual multiple flat warts seen in children it is found that such cases will not infrequently respond to the internal administration of mercury. Yellow mercurous iodide does well, and the dosage is to be governed in general by the age. It often seems advisable to increase the dosage gradually to the point where symptoms are felt from it, such as slight cramps or diarrhea, and the dosage maintained just below the amount necessary to produce these symptoms. The urine should be watched, of course, during this time. If no result on the warts is obtained within four to six weeks, it is inadvisable to continue this medication further.

Fractional doses of radiation with a thin aluminum filter have sometimes been helpful, but the dose should be carefully calculated and the treatment given by one with satisfactory experience in this field of roentgen therapy.

ERGOTAMINE TARTRATE FOR MIGRAINE

To the Editor:—Are there any harmful effects known to develop as a result of the prolonged use of ergotamine tartrate for the relief of migraine headaches?

L. J. Alger, M.D., Grand Forks, N. D.

ANSWER.—There have been no serious ill effects reported in the literature from the prolonged administration of ergotamine tartrate taken by patients with migraine. The drug, however, must be used with caution and it is advised to give not more than 0.5 mg. subcutaneously at a time and that such a treatment should not be repeated more than three or four times a week. It is unlikely that this would be the case, for most patients with migraine do not have recurrence of their attacks more often than every four to six weeks. If ergotamine tartrate is given more frequently than needed, the patient may have signs of inadequate peripheral circulation. The various symptoms from overdosage and the complications that may ensue have been discussed by von Storch. If huge amounts of ergotamine tartrate are given at one time, death may follow. Such a case was reported by Jervis and Kindwall.

ALLERGY TO TREE POLLENS IN TEXAS

To the Editor:—How long will the trees in Texas which cause spring allergy be active? A man suffers acutely of present with sneezing and eye irritation.

M.D., Texas.

ANSWER.—In the San Antonio area the cedar trees start blooming early in December and continue until rather late in February. Then the other trees begin blooming and one or another is blooming until early April, by which time it is all over. There is no one tree which blooms through all this period. The elms usually begin while the cedar is still blooming; then the hackberry, oak, cottonwood and others come on almost simultaneously. With the exception of cedar which has a rather long blooming season, the pollination time of the trees is short, as a rule not more than three or four weeks. The combined tree season, however, occupies a period of about four months.

H 11 FOR CANCER

To the Editor:—A patient has brought to me a clipping from a British newspaper in which reference is made to a treatment for cancer, H 11, which has been developed at the Hosa Research Laboratories, London. Will you kindly give me any information that you may have regarding this substance?

M.D., Ohio.

ANSWER.—The clinical use of an alcoholic fraction of urine known as H 11 in the treatment of malignant tumors has been advocated by Thompson on the basis that this preparation has the property of arresting experimental tumor growth in mice. The preliminary evidence presented by this author in support of his contention is far from convincing. Moreover, the anticarcinogenic property of H 11 has not been confirmed by three different groups of investigators. Its clinical use is thus unwarranted at present.

STUDIES ON THE DISTRIBUTION OF PENICILLIN IN THE EYE

AND ITS CLINICAL APPLICATION

LIEUTENANT COLONEL GILBERT C. STRUBLE

AND

MAJOR JOHN G. BELLOWES

MEDICAL CORPS, ARMY OF THE UNITED STATES

The remarkable success obtained in the treatment of severe infections with penicillin has naturally called attention to possible applications in ophthalmology. In general, the drug has proved to be very effective in the treatment of infections produced by *Staphylococcus aureus*, the pneumococcus, the hemolytic streptococcus, the gonococcus and the meningococcus. With the exception of the last two mentioned organisms, penicillin is relatively ineffective against gram negative bacteria. Encouraging results already have been reported following its employment in cavernous sinus thrombosis, corneal ulceration, conjunctivitis,¹ orbital and facial cellulitis² and acute gonorrheal ophthalmia.³

In corneal infections experimentally produced with *Staphylococcus aureus*, Robson and Scott⁴ found this drug to be very effective if applied within a reasonably short time. From these data they recommend that the local use of penicillin be given a clinical trial. Another investigator, von Sallmann,⁵ produced intraocular infections in rabbits by introducing pneumococci and *Staphylococcus aureus* into the anterior chamber. It was very effective against the pneumococcus and *Staphylococcus aureus* but ineffective in combating the ensuing endophthalmitis after intralenticular injections of *Clostridium welchii*.

The only work that has been done on the penetration and distribution of penicillin has been its determination in a few of the body fluids. Florey and his co-workers have demonstrated its absorption and excretion in blood and urine. They found penicillin in the whole blood, bile and saliva but none in the pancreatic juice or tears of cats given the substance intravenously. They have shown that penicillin does not become inactivated when incubated for three hours with slices of kidney, spleen, brain, muscle, lymph gland, lung and intestine

of rabbits. Rammelkamp and Keefer⁶ have investigated the absorption and excretion of penicillin after intravenous, intramuscular and subcutaneous injections. They found that penicillin failed to penetrate red blood cells in significant amounts (less than 10 per cent. of the plasma concentration) and that it failed to enter the spinal fluid, tears or saliva. Von Sallmann and Meyer,⁷ studying the penetration of the drug after local and systemic application, demonstrated penicillin in the aqueous humor; it was particularly high after iontophoresis. In two tests the vitreous humor was negative. When the administration was systemic, paracentesis led to a manifold increase in the secondary aqueous.

Since the efficiency of a chemotherapeutic agent depends not only on its potency but also on its diffusibility and concentration in the infected part, it was considered desirable that investigation be undertaken to secure information on the distribution of penicillin in the eye and other organs and body fluids.

EXPERIMENTAL STUDIES

A. Distribution After a Single Massive Dose.—General anesthesia was induced in dogs by the intravenous injection of sodium amytal (0.045 Gm. per kilogram of body weight). Then 12,800 units of penicillin per kilogram of body weight in a highly concentrated form (20,000 units per cubic centimeter solution) was injected intravenously. At specified time intervals blood samples were withdrawn, eyeballs enucleated and body tissues removed for analyses. Caution must be exercised in interpreting results, since the number of experiments performed was small. After removal of the eyeball the aqueous humor was aspirated and the globe dissected into the following components: lens, vitreous humor, cornea, sclera and chorioretinal layer. All tissues but the vitreous humor were immediately weighed and transferred to mortars, where they were thoroughly ground with sand mixed with a minimum volume of saline solution. It was found that no appreciable differences were obtained if the tissues were ground after rapid freezing or prepared in the usual manner. Each mixture was transferred quantitatively to a 15 cc. tube and centrifuged from five to ten minutes. The supernatant liquid and washings were combined and brought up to a specified volume. Aliquot portions were removed and assayed by the method developed by Florey and his associates. The Oxford writers admit that this test has a ± 25 per cent error, but they doubt if other methods are more accurate. They claim that their method has the advantage of being many times more rapid and can be carried out with small amounts of fluid. The vitreous humor

The laboratory investigation was carried out with the aid of Dr. K. K. Chen and his associates at the Lilly Research Laboratories, Eli Lilly and Company, Indianapolis.

(stirred vigorously until it became fluid), aqueous humor, blood and bile were tested without dilution.

Penicillin was found to penetrate into the eyeball with great rapidity. After fifteen minutes the penicillin content was found to be at its highest peak of concentration in the chorioretinal tissues and extraocular muscles. After the initial sharp rise, the aqueous humor and the relatively poorly vascularized conjunctiva and sclera showed a slow continuous increase until the end of the first hour. The blood penicillin was at its highest level directly after the injection and fell immediately. The concentration of penicillin was found to be in the following order: extraocular muscles, sclera, conjunctiva, blood, chorioretinal layer and the aqueous humor. The penicillin content of the vitreous humor and cornea was always less than 0.2 Oxford unit per gram of tissue, while the lens was consistently negative. The tears of dogs, contrary to the negative findings of Florey and his associates on the cat and of Rammelkamp and Keefer on man, showed a moderate concentration of penicillin (3.19 at fifteen minutes). The drug concentration in those tissues and fluids attaining the highest peak fell the most precipitously. Thus, in the first fifteen minutes the penicillin content of the extraocular muscle reached a concentration of almost 15 units per gram of wet weight, while at the end of sixty minutes it fell to about 6 units. On the other hand the penicillin content per gram of wet weight of the chorioretinal layer was 2.05 units in fifteen minutes and 1.39 units at the end of sixty minutes. At the end of three hours penicillin was completely absent from the blood, but the ocular fluids and media with the exception of the crystalline lens still showed a trace of this substance.

B. Penetration into the Eye After the Parenteral Administration of Penicillin in Approximate Clinical Doses.—Instead of employing a dosage far exceeding that employed clinically, dogs were given 1,500 units of penicillin per kilogram of body weight either by a slow intravenous drip over a period of five or six hours or divided into three intramuscular injections at two hour intervals. The blood tested at hourly intervals throughout the experiment was always negative. Likewise, the ocular fluids and tissues tested at the end of three, four, five and six hours were entirely negative with two exceptions, in which a trace was found: one was a sample of conjunctiva examined at the end of six hours of a continuous intravenous administration, and the other exception was a specimen of aqueous humor aspirated immediately after the third intramuscular injection.

C. Distribution of Penicillin in Eye After Subconjunctival and Topical Administration.—If penicillin can readily reach the ocular media and tissues following its subconjunctival and topical application, a more effective and economical method of therapy might be achieved by local application rather than by intravenous administration. Since the effective dose for various infections is yet unsettled and the dosage of penicillin largely arbitrary, it was advisable to determine the tolerance of the ocular tissues to the subconjunctival and topical administration of penicillin.

The application of a 5 per cent solution of metycaine as a surface anesthesia preceded the subconjunctival injection of penicillin in rabbits. Penicillin in 500, 1,000, 2,500 and 5,000 units dissolved in 0.25 cc. of isotonic solution of sodium chloride was injected. With the exception of the eyeball receiving the 5,000 unit

injection all globes showed a decreased amount of swelling in one hour, and the eyes were normal at the end of twenty-four hours except for the hyperemia at the point of injection. With the injection of 5,000 units, chemosis was pronounced at the end of one hour but at the end of twenty-four hours was greatly reduced. Since 2,500 units of penicillin was the highest concentration tested that was well tolerated, this quantity was used for the study of penicillin distribution following subconjunctival injection.

The reaction of the eyeball to topical applications of penicillin was tested on the corneas of rabbit and man. In the rabbit a constant contact of the cornea with a saline solution of penicillin containing as much as 20,000 units per cubic centimeter produced no staining with fluorescein or any other change visible to the naked eye. In man, solutions containing 10,000 units per cubic centimeter, dropped into the conjunctival sac produced only a slight smarting. Examination of the eyeball with the slit lamp and fluorescein staining revealed no alteration in the corneal epithelium.

(a) *Subconjunctival Injection:* After subconjunctival injections, eyeballs were removed at one-half and three hour intervals and the ocular tissues and fluids tested for the penicillin concentration. The penicillin content in the aqueous found with 2,500 units in this manner approximated that obtained by using forty times as much intravenously. The concentration reached in the cornea, vitreous humor, conjunctiva, sclera and iris with ciliary body exceeded many times that obtained by the intravenous route. Thus the cornea and vitreous humor, which barely showed a trace of penicillin when it was given intravenously by the subconjunctival route, reached the high value of 28 units in the cornea and 1.95 units in the vitreous humor (chart 3). One cannot rule out completely that leakage from the subconjunctival injection may lead to direct contact of the penicillin with the cornea. Unfortunately, after the intravenous injection the uveal and retinal tissues were not tested separately nor were they separated in anterior and posterior portions, so the value 2.03 units represents a mean of the entire retina and uvea. This value is in sharp contrast to the high values of 10.8 to 26.32 units per gram of iris and ciliary body obtained after the subconjunctival injection of much smaller amounts of penicillin. One disadvantage of the latter method is that the posterior uveal and retinal tissues showed little or no penicillin. Analyses of scleral tissue taken from the anterior portion of the globe gave values ranging from 163.23 to 194.40 units per gram, while those taken from the posterior portion of the globe showed a range from 92.54 to 93.31 units per gram. The conjunctival concentrations were extremely high, ranging from about 106 to 449 units per gram of tissue. In three hours most of the ocular tissues tested were essentially negative except for slight amounts in the aqueous and vitreous humors.

(b) *Topical Application:* Rabbits were anesthetized by intravenous injections of sodium amytal. An excess of solution containing 20,000 units of penicillin per cubic centimeter of isotonic solution of sodium chloride was placed in the conjunctival sac of the rabbit, and the lids were clamped sufficiently tight to prevent an escape of the fluid. At one-half, one and three hour intervals the eyes were irrigated with saline solution to remove any remaining penicillin. After enucleation of the eyeball, tests were made for the penicillin content in the manner already described. Chart 2 shows the rise in

concentration of penicillin in the aqueous humor. It reaches a value of 3.32 units per cubic centimeter in thirty minutes, a level maintained with little change for one and one-half hours; but at the end of the third hour an increase in the concentration was noted (14.2 units per cubic centimeter). The aqueous humor at this time was of amber color, resembling a dilute solution of the type of penicillin used in the experiment, showing that penicillin penetrates not only the cornea but also the chromatic material that is combined with it. The concentrations of the drug in the cornea and iris with ciliary body are very high. Although the penicillin content of the sclera following topical application was less than that obtained by subconjunctival injection, it was very much greater than that found after the intravenous injection (chart 3). Of all three routes employed, the topical application in the form of a prolonged corneal bath gives the highest value in the vitreous humor. The crystalline lens was always negative by any method of administration.

It was reasonable to expect that wetting agents having a definite influence in increasing the penetrability

Chart 1.—Concentration of penicillin in the blood, ocular tissues and fluids following a single large intravenous injection (12,800 units per kilogram).

of sulfonamides might have a similar effect in increasing the penetration of penicillin.⁸ However, the results were negative with an aerosol. In fact, there was a moderate decrease when penicillin was used with this wetting agent. Whether this resulted from a destruction of penicillin by the aerosol due to pH changes or from other factors was not determined. Other wetting agents should be investigated.

D. The Effect of Paracentesis on the Penicillin Content of the Aqueous Humor.—The effect of paracentesis on the amount of penicillin in the second aqueous was undertaken. Rabbits were anesthetized by intravenous injection of sodium amytal, and penicillin was injected intravenously. A moderate increase in the second aqueous was noted, confirming the observation made by von Sallmann and Meyer. In view of the fact that the aqueous was removed at fifteen and forty-five minute intervals, a period of time for the penicillin

concentration to increase normally (chart 1), it is quite possible that this noted increase might have been independent of the paracentesis. The experiment should be repeated with suitable controls.

E. Penicillin in the Tears.—Florey and his co-workers in England and Rammelkamp and Keefer in this

Chart 2.—Penetration of penicillin through the cornea.

country have reported the absence of penicillin in tears. After intravenous injection of 12,800 units of penicillin per kilogram of body weight the tears of dogs contained 3.15 units per cubic centimeter within fifteen minutes and 1.66 units per cubic centimeter within the second fifteen minute period. The effect of lysozyme in tears was ruled out by testing tears

Chart 3.—A comparison of the maximal concentrations of penicillin in eyeball following intravenous, subconjunctival and topical administration.

before administering penicillin. However, the possibility of increased diffusion of serum and penicillin from the underlying capillaries due to conjunctival irritation must be considered.

F. The Concentration of Penicillin in Other Body Tissues and Fluids.—In dogs, after the intravenous injection of 12,800 units of penicillin per kilogram of body weight, various tissues and fluids were collected

8. Bellows, J. G.: Chemotherapy in Ophthalmology, *Arch. Ophth.* 29: 888 (June) 1943. Bellows, J. G., and Wetting Agents in Ophthalmology with Compounds, *ibid.* 30: 352 (Sept.) 1943. at the end of one, two and three hour intervals. Table 1 shows that the concentration in the tissue is greatest at the end of the first hour and falls to a trace or becomes entirely negative within two or three hours. This gives substantial support for the clinical recommendation that penicillin be administered either by intravenous drip over a long period of time or by frequent intramuscular injections.

G. Clinical Trial of Penicillin in Ocular Infections.—The foregoing data make it apparent that topical applications of penicillin are the most suitable form of administration for external infections of the eyeball and its adnexa and that parenteral injections, although leaving much to be desired, are best suited for infections of the uveal and retinal layers particularly in the posterior segment. Table 2 summarizes the results of the topical application of penicillin for external ocular infections. In a total of 13 cases, gratifying results were obtained by penicillin drops. The concentration of the drug varied from 200 to 2,500 units per cubic centimeter.

• Equals trace of penicillin.

A less satisfactory response was observed in deep seated lesions even though penicillin was administered by intravenous or intramuscular injection. A total of 3 cases was studied. Two patients had chronic exudative choroiditis: one with a solitary lesion near the superior temporal periphery adjacent to an area of old healed chorioretinitis, and the other with a large confluent area of deep choroiditis in the inferior mid aspect of the fundus. Tuberculin tests in both cases were negative through the 1 to 10 dilutions. Syphilis and all possible foci of infection had been eradicated. The vitreous in both instances contained many opacities but not to such an extent as to prevent a view of the fundus lesions. Both patients were given a continuous intravenous drip of 100,000 units of penicillin for seventeen hours (in 1,000 cc. of isotonic solution of sodium chloride). This was followed by 100,000 units of the drug daily by intramuscular injection for the next two days. The 100,000 units was dissolved in 20 cc. of isotonic solution of sodium chloride so that each cubic centimeter contained 5,000 units. This was administered every three hours day and night. At the end of the seventy-two hours treatment neither case showed evidence of clinical improvement. Penicillin in the strength of 500 units per cubic centimeter was instilled every three hours day and night for ten days. At the end of that time both patients were again examined.

There was no appreciable change in the appearance of the fundus picture, vitreous opacities or visual acuity.

The third case was one of subacute bilateral iridocyclitis with a unilateral macular edema of the left eye. This patient's eye condition was believed to be due to a recent neisserian infection which had recurred on two occasions—once following a third course of sulfathiazole and once following an inadequate dose of penicillin. At this time the urethral discharge had entirely subsided and prostatic findings were negative. All foci of infection had been eliminated. The condition had progressed in spite of atropine and hot compresses locally and repeated intravenous injections of typhoid vaccine with a poor febrile response.

Prior to the intravenous and intramuscular administration of penicillin for three days as outlined, the visual acuity of the right eye was 20/20 and of the left eye 20/70. There were many cells in the aqueous of both eyes. At the completion of the therapy described the vision of the left eye had improved to 20/30. At that examination it was noted also that practically all the cells had disappeared from the aqueous of both eyes. One week later the vision had slipped in the left eye to 20/50—1 and a moderate number of cells were again present in the aqueous of both eyes. Pupillary dilatation had been maintained during this period.

This patient subsequently showed much improvement following two treatments in the fever cabinet, running the temperature up to 106 F. for five hours. One hundred thousand units of penicillin was administered intravenously over a period of a few hours during the fever therapy. The day following this first treatment the visual acuity of the left eye had improved to 20/20—2 Jaeger 1 and thereafter was staying at 20/15. All macular edema had subsided.

There was considerable clearing of the cells in the anterior chambers of both eyes following this regimen but there had been some slight recurrence of cells in the anterior chamber of the right eye during the past forty-eight hours.

Although the clinical data presented in this report are small, they bear out the conclusions reached theoretically that, in external disease in which local application of penicillin could be brought in high concentration on the infection, the infection cleared rapidly. Infections of the chorioretinal layers in which the penicillin concentration was slight even after massive intravenous dosage showed little response.

COMMENT

The ready permeability of most of the tissues after the intravenous injection of penicillin is undoubtedly an important factor in its therapeutic efficacy. However, some very important exceptions exist: the cornea, lens, vitreous humor, cerebrospinal fluid, nerve, brain, dura and bone marrow show little or no penicillin after such injections. In one experiment erratic results were obtained with bone marrow. It must be emphasized that some preparations of penicillin have enormous potency and are effective in dilutions of over 1 to 100 million. Since amounts less than 0.1 to 0.2 unit are not measurable by Florey's method, it is still possible that bacteriostatically effective concentrations may be present in some of these tissues and organs.

Certain organs and tissues apparently extract large amounts of this substance from the blood stream and eventually may contain a concentration greater than that of the blood. For example, the extraocular muscles contain almost 15 units per gram of wet weight

within fifteen minutes, and the less vascularized tissues, such as the conjunctiva and sclera, obtain their maximum concentrations of 13 and 14 units per gram of wet weight at the end of sixty minutes. These values are about three times as high as that found in the blood at its peak, which is immediately after the injection. The data here presented suggest the possibility that some tissues may have a selective absorption for penicillin. The highest peak reached in the aqueous humor is at the end of one hour, resembling in this respect the conjunctiva and sclera. Both the aqueous humor and uveal and retinal tissues show but small amounts of penicillin, and therefore the decline is not as precipitous as in the case of those tissues which contain large amounts of penicillin (chart 1). The avascular

Even at the end of three hours, when all other tissues and fluids are either negative or show only a trace of the drug, the bile contained about 5 units of penicillin per cubic centimeter (table 1). The Oxford investigators incubating penicillin with blood and various tissues at 37 C. for three hours observed no decrease in the potency of the drug. The intravenous or intramuscular injection of penicillin in dogs in therapeutic dosage gives a concentration of penicillin in the blood and most tissues too small to be detected by the usual methods of assay. Since it is advisable to give penicillin in large doses so as to prevent organisms (particularly the staphylococci) from becoming penicillin fast, it seems from the data reported here that the dosage which is considered by some clinicians to be sufficient,

TABLE 2.—Results of Topical Application of Penicillin for External Ocular Infections

Patient	Diagnosis	Cultures	Medication	Results
N. L. W.	Chronic catarrhal conjunctivitis O. U.; granular blepharitis	Penicillin drops, 200 units per cc.	Conjunctivitis cured in 24 hours; blepharitis unimproved
W. W. W.	Acute catarrhal conjunctivitis	Gram negative diplobacilli and hemolytic Staph. albus	Penicillin drops, 500 units per cc.	Control eye treated with 0.25% zinc sulfate; penicillin treated eye cured in 48 hours; control eye cured in 72 hours
M. H.	Acute hypertrophic catarrhal conjunctivitis with follicles O. D.; no preauricular glands; 10 days later similar onset in O. S.	Two cultures negative; third culture showed 1 colony of non- hemolytic Staph. albus	Penicillin drops, 200 units per cc.; later 500 units per cc.	Right eye (first involved) required 10 days for clinical cure; left eye cured in 3 days on 500 units per cc. solution
H. C. B.	Acute catarrhal conjunctivitis O. S.	Few bacteria only, not identified	Penicillin drops, 200 units per cc.	Cured in 24 hours
J. B. O.	Pure culture; Strep. viridans	Penicillin drops, 500 units per cc.	O. S. very much improved in 24 hours; cured in 48 hours; O. D. cured in 36 hours
H. C. H.	Acute catarrhal conjunctivitis O. U.	No growth	Penicillin drops, 500 units per cc.	Both eyes cured in 48 hours
R. S. S.	Acute catarrhal marginal ulcer O. S.	Nonhemolytic Staph. albus	Penicillin drops, 200 units per cc.	Cured in 12 hours; patient had had similar episodes previously, not treated with anything, which re- solved in 12-24 hours
D. B.	Acute catarrhal conjunctivitis O. D.	No growth	Penicillin drops, 500 units per cc.	Cured in 24 hours
H. B. G.	Chronic catarrhal conjunctivitis O. U.; 15 years' duration with recurrent bouts of pain, redness and tearing; allergic studies negative; somewhat improved O. U.; autogenous vaccine over 8 months' time	Staph. albus and diptheroids	Penicillin drops, 500 units per cc.	Lids much improved in 72 hours; penicillin continued for 3 weeks; objectively and subjectively there was great improvement
O. F. H.	Right acute episcleritis 1 day's duration	Penicillin drops, 2,500 units per cc.	Eyo white in 24 hours
R. S.	Acute conjunctivitis O. D.; first noticed on awakening	Penicillin drops, 2,500 units per cc.	Much improved in 24 hours; normal in 48 hours
C. M.	Acute catarrhal conjunctivitis O. U.	Hemolytic Staph. albus	Penicillin drops, 500 units per cc.	Much improved in 24 hours; normal in 48 hours
A. F. B.	Acute conjunctivitis	Culture and smears negative	Penicillin drops, 2,500 units per cc.	Objectively and subjectively normal

cornea and vitreous humor either contained no penicillin or at the most showed a quantity less than 0.2 unit per gram of tissue. The factors that the lens is avascular and is surrounded by a capsule which may serve as a barrier are probably important in explaining its constant negative test.

The very high penicillin content in the kidney (17.38 units per gram) is not surprising in view of the fact that this organ is active in the excretion of the drug. Of possible clinical importance are the surprisingly high amounts found in the lungs (8.91 units per gram), skin (6.06 units per gram), buccal mucosa (8.36 units per gram), small intestines (9.68 units per gram), bile (6.65 units per cubic centimeter) and liver (4.77 units per gram). The saliva, contrary to the negative report of Rammelkamp and Keefer, showed a slight amount of penicillin.

It is interesting to speculate where the penicillin is "lost." Florey and his associates have demonstrated that the entire loss cannot be accounted for by the amount appearing in the urine. It is noteworthy that the bile contains a very high concentration of penicillin.

that is, 100,000 units daily for a 70 Kg. person, is really inadequate.

When penicillin can be applied topically, an enormous concentration can be achieved locally, which surpasses by far any value which can be secured even by the most massive intravenous doses. This procedure has the further advantage of saving a considerable amount of the drug. Subconjunctival injection up to 2,500 units and topical administration of a concentration up to 20,000 units of penicillin are well tolerated by the rabbit. By these means extremely high concentrations can be obtained in the tissues of the anterior segment of the eyeball. It must be pointed out that the rabbit's cornea has been shown to be more permeable to sulfonamides than those of the dog and man. A similar difference may exist with penicillin. Whether this variation in permeability is due to the reported differences in the thickness of the cornea is unknown. Friede⁹ states that the thicknesses of the central por-

9. Friede, R.: Vergleichende Studien zur Grösse der tierischen und menschlichen Hornhaut mit besonderer Berücksichtigung der menschlichen Megalcornea, Arch. f. Ophth. 131:1, 1934.

tions of the corneas of rabbit, dog and man are 0.8, 0.9 and 0.9 mm. respectively. At the periphery the thickness is even greater in man. However, the concentration reached in the anterior segment of the eyeball is so great that, even if the penetration in man should be only a small fraction of that found in the rabbit, the amount reaching the cornea, conjunctiva, sclera, aqueous and the anterior uvea will still be adequate for therapeutic effectiveness.

The amount of penicillin reaching the vitreous chamber, although slight, is much more than what can be obtained even after very massive intravenous doses. The extremely high corneal penetration reached after three hours of constant corneal bath with penicillin is surprising (chart 2). The constant moderate value for two hours followed by the rapid rise after that time suggests a change in corneal permeability permitting an increased penetration.

It would seem from the results of our investigation that, if the efficacy of the drug is dependent only on its concentration (an assumption for which there is no proof), the local application of penicillin to the eyeball should be effective in those infections with organisms susceptible to the action of penicillin, involving conjunctiva, cornea, sclera, anterior chamber, iris with ciliary body, and vitreous. Similar infections involving the posterior uvea and retinal layers will require the parenteral administration of large amounts of penicillin. But even after huge amounts the penicillin content in these tissues is low.

Bearing out these laboratory findings are the clinical results. Infections involving conjunctiva and cornea respond rapidly to penicillin locally. Infections involving the posterior uveal tissues seem uninfluenced even after massive intravenous doses.

SUMMARY

1. Penicillin can be detected in the eyeball within fifteen minutes after a large intravenous injection. The concentrations of the tissues and fluids examined, listed in decreasing order, are as follows: extraocular muscles, sclera, conjunctiva, tears, chorioretinal layer, aqueous humor, vitreous and cornea. The crystalline lens is negative. The value in the blood is highest immediately after the injection, drops to about half of the original level in one hour and is down to zero at the end of three hours. The extraocular muscle has its greatest concentration in fifteen minutes and drops precipitously from then on. The aqueous humor and the less vascularized tissues such as the conjunctiva and sclera after their initial sharp rise within the first fifteen minutes continue to increase slowly until the end of the first hour. Barely a trace of penicillin remains in the eyeball after three hours.

2. Penicillin administered intravenously and intramuscularly in amounts comparable to therapeutic doses ordinarily reaches such a slight concentration in the fluids and tissues that it is not measurable by the usual methods.

3. After subconjunctival injection, high and even enormous concentrations are reached in the cornea, iris with ciliary body, conjunctiva and sclera. There is a moderate amount in aqueous and vitreous humors. The posterior half of the chorioretinal layer and the lens show negative results. After a constant corneal bath of penicillin the results are similar, except that the concentrations in the aqueous, cornea, vitreous and iris with the ciliary body are higher and those in the conjunctiva and sclera are lower.

4. One hour after a huge intravenous injection of penicillin the body tissues and fluids examined, listed in decreasing order, are as follows: kidney, small intestine, lung, buccal mucosa, bile, skin, liver, adrenal, pancreas, heart, voluntary muscle and spleen. At the end of three hours all the tissues and fluids examined, except bile, show little or no penicillin. Bile at that time still retains 5 units of penicillin per cubic centimeter.

5. The clinical results of local application of penicillin in external ocular disease are encouraging. In a few deeply situated inflammatory lesions of the eye, little or no improvement is noted in spite of huge doses of penicillin given intravenously.

PENICILLIN IN THE TREATMENT OF OPHTHALMIA NEONATORUM

JEROME J. SIEVERS, M.D.

LESLIE W. KNOTT, M.D.

AND

HERMAN M. SOLOWAY, M.D.

SPRINGFIELD, ILL.

Although the sulfonamides have been of great value in the treatment of ophthalmia neonatorum, certain problems have arisen in connection with their use which seemed to justify a study of the effects of penicillin.

For several years the Illinois Department of Public Health has provided hospitalization and treatment for patients with ophthalmia neonatorum. The plan provided for immediate hospitalization of the infant in a centrally located hospital where the services of an ophthalmologist and a pediatrician were available. The infants were treated with sulfonamides orally and with irrigations locally. Although no blindness resulted in some 35 cases so treated, it was found that many infants were either intolerant to the sulfonamides or quickly became resistant. Prolonged hospitalization usually was necessary before the infant could be discharged as clinically and bacteriologically cured.

STUDY

Through the courtesy of the Committee on Chemotherapeutics and Other Agents of the National Research Council, a limited supply of penicillin was made available to study its effect on ophthalmia neonatorum.

Of the 8 cases included in this study, 5 showed gram-negative intracellular diplococci on smear and organisms giving a positive oxidase reaction and fermentations typical of gonococci on culture.

Two cases showed gram-negative intracellular diplococci on smear and oxidase positive colonies of gram-negative diplococci on culture. The organisms isolated from these two cultures failed to grow on subculture.

In 1 case the etiologic agent could not be determined, although the clinical findings were typical of ophthalmia neonatorum (case 7).

Because of the lack of precedent it was necessary at the beginning of the study to outline more or less arbitrary procedures with respect to both the dosage of penicillin and the criteria of cure.

Ten thousand units of penicillin injected intramuscularly at intervals of three hours for a total of six injections.

From the Illinois Department of Public Health, Roland R. Cr... M.D., Director.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

tions was selected as the original treatment schedule. Later this was felt to be inadequate and the dosage was adjusted individually for each case (table 1).

The criteria of cure chosen were (a) absence of clinical activity, (b) three consecutive negative smears for gram-negative intracellular diplococci and (c) three consecutive negative cultures for gonococci.

All patients received instillations of 0.5 per cent atropine sulfate and irrigations of sterile water during the acute clinical phase of the infection.

REPORT OF CASES

CASE 1.—A Negro girl born Nov. 19, 1943, with onset November 20, admitted November 23, received a total of 39 grains (2.5 Gm.) of sulfadiazine in several courses together with 2 per cent sulfathiazole solution irrigations in both eyes between the date of admission and Jan. 8, 1944. Sulfadiazine was stopped because of persistent vomiting. Smears and cultures from both eyes were positive for gonococci on January 8, and examination revealed moderate swelling and injection of both conjunctivas with a moderate amount of purulent exudate. The corneas were normal. The patient was given 60,000 units of penicillin intramuscularly over a fifteen hour period. Definite clinical improvement was noted at the end of twenty-four hours; there was no further discharge. Both eyes were clinically normal within three days and remained so thereafter. Cultures and smears became negative on the 2d day following completion of penicillin therapy. Except for one positive culture from the right eye on the 3d day, all cultures and smears remained negative.

CASE 2.—A white boy born Dec. 10, 1943, with onset December 22, admitted Jan. 10, 1944, received no treatment prior to admission other than silver nitrate prophylaxis at birth. Examination revealed moderate redness and swelling of both eyes externally. The conjunctivas were injected, and a frankly purulent discharge was present bilaterally. The corneas were clear. The patient received 60,000 units of penicillin intramuscularly during a fifteen hour period. Because of persistent clinical and laboratory findings a second course of 90,000 units (15,000 every three hours) was given on the 5th day of hospitalization but failed to effect any improvement. A short course of sodium sulfadiazine during the 13th to 16th hospital days likewise failed to elicit any response. On the 23d and 24th days a third course of penicillin was administered, 20,000 units for six doses followed by 10,000 units for six doses. The conjunctivitis continued unabated, and smears and cultures remained positive. Recovery finally occurred after the use of sulfonamides combined with foreign protein therapy.

CASE 3.—A Negro boy born Jan. 12, 1944, with onset January 17, admitted January 18, had been given silver nitrate prophylaxis at birth and boric acid solution irrigations following the onset. Intense swelling and redness of both eyes externally and pronounced chemosis and injection of the palpebral conjunctivas with a frankly purulent exudate were noted on admission. No corneal involvement was found. Over a fifteen hour period 120,000 units of penicillin was administered intramuscularly. Considerable improvement occurred in both eyes within eight hours after the beginning of therapy. Chemosis and injection gradually subsided, so that both eyes appeared normal on the 6th day of hospitalization and remained so thereafter. Following treatment, smears failed to show any intracellular diplococci and all cultures were negative.

CASE 4.—A white girl born Jan. 12, 1944, with onset January 27, admitted January 28, had been treated with silver nitrate at birth. On admission the right eye showed moderate swelling externally, a purulent discharge and injection and chemosis of the conjunctiva. The only involvement of the left eye consisted of slight conjunctival injection. The corneas were clear bilaterally. Initial smears and cultures revealed both gonococci and *Haemophilus influenzae*. The patient received 180,000 units of penicillin intramuscularly over a period of thirty-four hours (6 doses of 20,000 units followed by six doses of 10,000 units). Definite improvement was noted in nine hours, and both eyes were clinically normal on the 4th hospital day and remained so. Following the initial laboratory findings

all cultures were negative for gonococci, and smears failed to show any intracellular gram-negative diplococci. Organisms resembling *Haemophilus* were seen in small numbers in both smears and cultures periodically throughout observation.

CASE 5.—A Negro girl born Jan. 31, 1944, with onset February 3, admitted February 4, with delivery by a midwife, received no treatment prior to admission. The left eye showed external swelling and redness with a frankly purulent discharge. The left palpebral conjunctiva was injected and chemotic. There were minimal findings in the right eye. The corneas were clear bilaterally. During thirty-six hours 180,000 units of penicillin was administered intramuscularly. Improvement was noticeable after the 2d injection, and the eyes were practically normal twenty-one hours after the beginning of therapy. All cultures were negative after completion of therapy, and smears failed to show any intracellular gram-negative diplococci.

CASE 6.—A Negro boy born Jan. 23, 1944, with onset January 28, admitted February 4, had been given only silver nitrate prophylaxis at birth. External redness and swelling, chemosis and purulent discharge were all present in the left eye. Minimal findings were seen in the right eye. The corneas were clear bilaterally. Initial smears were typical for gonococci in the right eye, and a culture revealed oxidase positive colonies of gram-negative diplococci which failed to grow on transplants and could not therefore be confirmed. The patient received

TABLE 1.—Results of Treatment of Ophthalmia Neonatorum with Penicillin

Case No.	Duration of Infection, Days	Etiologic Agent	Total Penicillin, Units	Beginning of Improvement, Hours	Clinical Cure, Days	Laboratory Cure, Days	Final Results
1	47	N. gonorrhoeae	60,000	24	3	0	Satisfactory
2	20	N. gonorrhoeae	330,000*	Unsatisfactory
3	2	N. gonorrhoeae	120,000	0	6	7	Satisfactory
4	2	N. gonorrhoeae, H. influenza (?)	180,000	0	4	6	Satisfactory
5	2	N. gonorrhoeae	180,000	6	6	24	Satisfactory

* 60,000 units 1st day, 90,000 units 4th day, 180,000 units 22d and 23d days.

180,000 units of penicillin intramuscularly during a thirty-two hour period. At the time of the 4th injection definite clinical improvement was noted and by the 5th hospital day both eyes were clinically normal. All subsequent smears and cultures were negative following completion of therapy.

CASE 7.—A white boy born Feb. 21, 1944, with onset February 28, admitted March 1, had received silver nitrate prophylaxis at birth and instillations of mild protein silver during the three days following onset. The right eye was moderately involved with external redness and swelling, inflammatory chemosis and a purulent discharge. Slight conjunctival findings were present in the left eye. No gonococci were found in the initial smears or cultures, but in the latter several colonies of diphtheroids were isolated. These proved to be avirulent in guinea pigs. There were no other findings which helped to determine the etiologic agent, and smears taken from the child's mother proved negative for gonococci. Penicillin was administered intramuscularly every three hours, 15,000 units in each of six doses followed by 10,000 units for fourteen doses (total 230,000 units). Specific therapy was prolonged in this case because of its failure to effect adequate improvement in clinical findings at the end of fifteen hours. At the completion of therapy moderate improvement was noted, but for the next thirteen days the condition remained static and complete recovery was not achieved. Following a short course of sodium sulfadiazine during the 17th to 19th hospital days, both eyes quickly returned to normal. Smears and cultures failed to reveal any significant organisms throughout the entire period of observation.

CASE 8.—A white boy born Feb. 19, 1944, with onset February 22, admitted March 17, concerning whose treatment prior to admission no information was available other than silver nitrate prophylaxis at birth, exhibited a bilateral purulent conjunctivitis at the initial examination. The conjunctival surfaces of the upper lids were granular. The corneas were not involved. Initial smears were typical for gonococci, and culture revealed oxidase positive colonies of gram-negative diplococci, which failed to grow on subcultures and could not therefore be confirmed. The patient received 20,000 units of penicillin intramuscularly every three hours for twelve doses (total 240,000 units). Definite clinical improvement was noted

* Cultures showed oxidase positive colonies of gram-negative diplococci which failed to grow on subculture and therefore could not be confirmed. S = smear, C = culture, P = positive, gram-negative intracellular diplococci in smears or gonococci in confirmed cultures, D = doubtful, gram-negative extracellular diplococci in smears, N = negative smear or culture, no gonococci.

at the time of the 9th injection, and both eyes were clinically normal by the 5th hospital day. Smears and cultures reverted to negative on the 2d day of therapy and remained so thereafter.

COMMENT

Clinical Response.—All except 2 of the 8 cases in this series responded to therapy within twenty-four hours, as manifested by subsidence of active inflammation. Case 2 and case 7 showed some improvement during and immediately after penicillin therapy but, instead of progressing to complete recovery as did the other 6 cases, again developed signs of active inflammation. Repeated courses of penicillin in case 2 produced the same initial response of short duration, followed by relapse.

Because of the large amount of penicillin given initially in case 7, it was not felt that a repeated course would be effective.

In the 6 cases that responded to the specific therapy, clinical recovery occurred in from three to six days, with complete absence of purulent discharge, chemosis and injection.

No corneal complications developed in any of the 8 cases.

As can be seen in cases 1, 3, 4, 5 and 6, occasional gram-negative extracellular diplococci were found on smears taken at varying intervals, even though cultures remained negative and the eyes were clinically normal. No further treatment was given and these cases were kept under observation until three consecutive negative smears and cultures were obtained.

Because of the persistence of clinical activity in case 2, treatment was continued despite the three consecutive negative smears and cultures obtained early in the period of observation, and later both smears and cultures were again found positive.

The treatment progress of each case is outlined in table 1.

Bacteriologic Response.—Smears and cultures were taken in all cases before beginning therapy, at the time of the third injection of penicillin and at intervals thereafter until the bacteriologic criteria of cure as outlined had been fulfilled.

As shown in table 2, all cases except 2 and 8 showed the absence of gram-negative intracellular diplococci in the smears taken at the time of the third injection, although smears in cases 4, 5 and 6 showed the presence of extracellular organisms. Cases 1 and 2 also gave positive cultures at this time, but cultures for all other cases were negative.

Of those cases that responded to penicillin, only 1, case 1, showed a positive culture after the 3d injection of the drug.

Reactions.—A possible reaction to penicillin was observed in case 2. Four days after the second course of penicillin a generalized papular eruption occurred and gradually subsided. Following the third injection of the third course the patient developed a generalized vesicular rash, which subsided during the following ten hours even though penicillin injections were continued. The day after completion of the 3d course a typical urticarial eruption was noted on the trunk and scalp. Although no additional penicillin was administered, the child continued to develop periodic allergic skin manifestations in the form of vesicular, urticarial and pustular lesions.

SUMMARY

1. Eight cases of ophthalmia neonatorum were treated with intramuscular injections of penicillin in total dosages varying from 60,000 to 330,000 units.

2. In 5 of the 8 cases the etiologic agent was definitely established as *Neisseria gonorrhoeae* by confirmatory fermentation tests; in 2 of the cases gram-negative intracellular diplococci gave positive oxidase reactions when grown on chocolate agar but could not be subcultured for confirmatory fermentation tests; in 1 case the infective agent could not be determined.

3. Six of the 8 cases responded promptly to penicillin with pronounced clinical improvement within twenty-four hours and complete recovery within three to six days.

4. The disappearance of specific organisms in smears and cultures was noted in from nine to twenty-four hours after beginning treatment with penicillin.

PHLEBOTOMUS (PAPPATACI OR
SANDFLY) FEVER

A DISEASE OF MILITARY IMPORTANCE

SUMMARY OF EXISTING KNOWLEDGE AND PRELIMI-
NARY REPORT OF ORIGINAL INVESTIGATIONS

(Concluded from page 606)

CLINICAL MANIFESTATIONS

Since there is as yet no specific diagnostic test for the individual case of Phlebotomus fever, it has always been difficult to know which variations from the typical syndrome could be correctly interpreted as manifestations of the same disease. During the course of various experiments in the present investigation more than 100 cases of the experimentally produced disease were observed. The following description of the various clinical manifestations is based on these observations:

Incubation Period.—Following intracutaneous injection of the virus, approximately 95 per cent of the persons developed the disease after an incubation period of about two and one-half to six days. There was 1 case after seven and nine days each and 1 probable case after fifty hours. Following intravenous inoculation, however, an incubation period of forty-two to forty-four hours was observed in 7 persons.

Fever.—Fever is unquestionably the most constant and, on occasion, perhaps the only sign. A few persons were encountered who developed the leukocyte changes characteristic of the disease without exhibiting any fever. Approximately 65 per cent had temperatures of 102 F. or more. Temperatures higher than 104.5 F. were not encountered, and only about 8 per cent had temperatures between 104 and 104.5 F.; only about 2 per cent had temperatures under 100 F. The duration of fever varied from part of one day to as long as nine days. The two, three and four day fevers, however, constituted 85 per cent of the total. In table 1 the duration of fever in 100 cases of experimental Phlebotomus fever is compared with that observed by Simmons, St. John and Reynolds¹⁸ in 81 cases of experimental dengue. Although in dengue also the duration of fever may vary from one to nine days, it is noteworthy that the five, six and seven day fevers constitute about 80 per cent of the total. Some of the varieties of temperature curves encountered in experimental Phlebotomus fever are shown in figure 3. The peak is reached on the first or second day and defervescence is usually gradual. Occasionally the temperature rises again after it has been normal for a day. Multiple cycles of fever will be described later under recurrences.

Pulse Rate.—On the first day of the disease the pulse rate is usually elevated, sometimes in proportion to the fever. Thereafter it returns to normal more rapidly than the temperature. A true bradycardia is not always present, but when it occurs it is observed in the range of 42 to 60 at the end of the febrile period

and during convalescence. The blood pressure is frequently low during the disease and convalescence.

Signs and Symptoms.—The disease is sudden in onset in the majority of cases. In some it is preceded by constipation, abdominal distress, giddiness and generalized malaise. The following signs and symptoms were encountered at the onset or sometime during the course of the disease, although many of them were frequently absent in otherwise typical cases:

1. Headache, usually severe and characteristically frontal or behind the eyes.
2. Burning sensation or pain in the eyes especially on movement; photophobia.
3. Generalized malaise, stiffness of the neck and back, backache especially in the sacroiliac region, and rheumatic-like pains in the joints and extremities.
4. Anorexia, nausea and not infrequently vomiting associated with ill defined abdominal distress. Constipation is more common at onset and diarrhea at the end of the disease and during convalescence.
5. Mild soreness of the throat and occasionally epistaxis.
6. Chilliness or short chills, but not real shaking chills, at the onset or during first two days.
7. Profuse perspiration during the course of the disease and preceding defervescence.
8. Giddiness or dizziness associated with great fatigue or weakness, especially during convalescence.

On physical examination one is frequently struck by the flushed or scarlet appearance of the face and neck, strongly resembling the acute erythema which follows sunburn. The conjunctival vessels may be decidedly congested, and this congestion is occasionally limited to the exposed portion of the ocular conjunctiva. The eyeballs may be very tender to the touch and painful on movement in any direction. In the mouth one may find congestion of the fauces, soft palate and posterior pharyngeal wall, but the pronounced swelling or redness of the tissues seen in bacterial infections of the throat was not encountered. Although some writers¹⁹ have described crops of vesicles without any inflammatory reaction at the junction of the hard and soft palates in natural cases of the disease, they were not observed in this series of experimental cases. Nasal catarrh and bronchitis are not a part of this disease. No objective evidence of nuchal rigidity was observed in any patient complaining of pain or stiffness in the back of the neck. The skin is hot and excepting the erythema of the face, neck and occasionally of the anterior part of the chest (and the papules resulting from insect bites on the exposed parts which may sometimes be found in natural cases) rarely present a true rash. There are certain exceptions, however. In the present experi-

18. Simmons, J. S.; St. John, J. H., and Reynolds, F. H. K.: Experimental Studies of Dengue, Philippine J. Sc. 44: 1, 1931.

mental series inoculated with serum virus 1 patient presented a generalized rash resembling both urticaria and erythema multiforme during the entire febrile period, which in his case was five days. Another presented an erythematous, maculopapular eruption which appeared on the second day of the fever over the lower halves of the posterior aspect of both thighs; the papules ranged in size from 2 to 8 mm. in diameter, were confluent in part and faded on pressure; there was no itching, and it became scaly on the fifth day. Certain other patients presented minute, indefinite erythematous blotches about the sebaceous follicles especially low in the axillas, on the lateral aspects of the chest and abdomen and around the elbows and knees. One patient presented large purpuric areas which appeared spontaneously around both knees. It should be stressed, however, that 90 to 95 per cent of the cases presented no eruptions of any kind. Occasional skin rashes of similar type were also observed by one of us (A. B. S.) in natural cases of the disease among

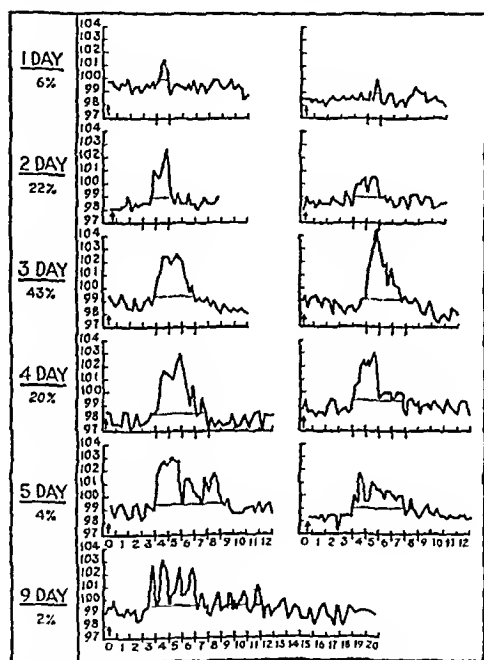

Fig. 3.—Various types of fever produced by experimental inoculation of *Phlebotomus* fever virus in human beings.

American troops in Sicily. Franz, writing in 1909 in the monograph by Doerr, Franz and Taussig,¹ makes similar observations and states that when careful examination was made some sort of skin involvement could be found in about 30 per cent of the cases, exclusive of the facial erythema and insect bites. It may be of interest that herpes simplex did not develop in any of our experimental cases, and we have seen it only once among some hundreds of natural cases.

The remainder of the physical examination was as a rule negative. The liver and spleen were not palpable. It is noteworthy that lymphadenopathy, which is common in natural and experimental dengue,¹⁸ did not occur or was uncommon in *Phlebotomus* fever.

The systemic symptoms disappear in some while the temperature is still elevated, while in others they may persist after defervescence. Convalescence is variable—some feel fit even before the fever has completely returned to normal, while others remain giddy, weak and depressed for varying periods thereafter.

Complications or Sequelae.—Only a few complications developed among more than 100 of our experimental cases. Two patients developed urinary retention at the end of the febrile period requiring catheterization; this lasted only a few days, however. One of the volunteers, who had "encephalitis with diplopia" six years before, again developed diplopia of about one week's duration during his convalescence from *Phlebotomus* fever. In 1 of the patients who had fever for nine days (fig. 3) with characteristic leukopenia an x-ray film of the chest taken ten days after onset revealed a large area of consolidation in the basal portion of the right upper lobe. This was not associated with any symptoms of lower respiratory involvement since there was no cough, expectoration, pain in the chest, dyspnea or increased respiratory rate. The consolidation had resolved to a considerable extent nine days later. With these exceptions, recovery was uneventful in all instances.²⁰

CLINICAL LABORATORY DATA

Observations were made on the urine, the cerebrospinal fluid and the blood, including determinations of the erythrocyte sedimentation rate, serum phosphatase and the Hanger²¹ cephalin-cholesterol flocculation test for liver damage.

Urine.—The urine of a number of volunteers was tested daily during the course of the disease and convalescence without the discovery of any abnormalities. The occasional dark color seemed to be due to concentration; tests for bile were uniformly negative. No real albuminuria was encountered during the febrile period; in less than 3 per cent there was a transitory faint trace reaction.

Cerebrospinal Fluid.—Lumbar punctures were performed on 5 volunteers: 2 on the first day and 3 on the second day of the disease. The cerebrospinal fluid was not under increased pressure and was normal as regards cells, protein, sugar, chlorides and the colloidal gold test. Inoculation of this fluid into susceptible human beings did not produce the disease, while the blood serum from the same volunteers did.

Blood.—No change in the number or character of the erythrocytes was found. The changes in the leukocytes, however, constitute the only positive clinical laboratory finding in this disease. During the course of this investigation it was realized that repeated total and Schilling differential leukocyte counts were necessary to establish whether or not the disease had been produced in any 1 individual. To date approximately 2,000 total counts and smears have been studied on over 150 human beings, and the following remarks will be based entirely on the observations made on persons with the experimental disease. The occurrence of a leukopenia in this disease has been known for many years¹ and the appearance of many immature neutrophils in natural cases has been reported more recently.²² However, the quantitative relationships of the various types of cells to one another at different times during the febrile period and convalescence have not been sufficiently appreciated heretofore and are of the greatest

20. One pool of serums obtained from patients in the Meiji Era apparently contained the "virus" of infectious hepatitis as well as that of *Phlebotomus* fever. Four of 10 volunteers inoculated with the "virus" developed jaundice two to four months later. The "virus" of infectious hepatitis seems to have been eliminated, however, by one passage through *Phlebotomus papatasi*.

importance in aiding diagnosis. The following points learned during the present investigation can be of great help in the diagnosis of *Phlebotomus* fever:

1. The disease may or may not be associated with a true leukopenia, but a pronounced relative and absolute reduction in the number of segmented neutrophils associated with a simultaneous definite relative and absolute increase in immature neutrophils (chiefly the staff cells) is a constant phenomenon (tables 2 and 3).

2. When leukocyte counts are done daily during the febrile and postfebrile periods a leukopenia, i. e. a reduction to below 5,000 cells per cubic millimeter from a higher normal level, may be expected in approximately 90 per cent of the cases.

cells increase to a point at which they usually outnumber the segmented cells.

6. Unless differentiation is made between the segmented and the immature cells (or filament and non-filament cells) the significant changes in the neutrophils may be missed, since the total percentage of these cells may never be less than 50 to 60. A reduction in neutrophils to as low as 30 per cent, even when the total leukocyte count is less than 5,000, is not compatible with a diagnosis of *Phlebotomus* fever unless the immature cells make up a large proportion of all the neutrophils.

7. The changing relationships between the different types of cells at various stages of the disease shown

3. A leukopenia is rarely encountered on the first day of the fever but is more often seen later, especially at the end of the fever and during the first two days of the postfebrile period (fig. 4).

4. The characteristic finding on the first day of the fever is a total count within normal limits, a relative and absolute decrease in the lymphocytes, and a relative and sometimes absolute increase in neutrophils which is due to an increase in immature cells. The total number of segmented neutrophils is usually not decreased at this time.

5. During the second or third days of the fever the number of lymphocytes begins to return to normal and for a few days thereafter may constitute 40 to 65 per cent of the total. At the same time the number of segmented neutrophils begins to drop and the immature

in figures 5 and 6 are more important for diagnosis than any single observation. The normal picture usually returns five to eight days after defervescence. The dromedary type of curve for the immature cells is commonly found when daily counts are done. There appears to be a point, during the febrile or postfebrile periods, at which both the immature and the segmented neutrophils are decidedly depressed.

8. Degenerative changes, in the form of toxic granules and vacuolation of the cytoplasm, may be seen in the neutrophils, but they are not sufficiently constant or striking to be useful in diagnosis.

9. The monocytes are usually normal in number and appearance. In certain patients, however, they increase in number to constitute 16 to 40 per cent of all the leukocytes during the febrile and early postfebrile periods.

10. The eosinophils occasionally disappear during the course of the disease. An eosinophilia during convalescence was encountered only among those who had it before inoculation.

Erythrocyte Sedimentation Rate.—Although the number of determinations has not been large, it was found that the erythrocyte sedimentation rate may be unaffected in some even after several days of high fever, while in others a slight to moderate increase in sedimentation may occur.

Phosphatase and Hanger Cephalin-Cholesterol Flocculation Test for Hepatic Damage.—Serum phosphatase determinations on 5 subjects on the 1st, 3d, 4th or 5th days after onset of the fever yielded normal values, i. e. 2.1 to 5.4 Bodansky units per hundred cubic centimeters. The Hanger cephalin-cholesterol flocculation test was carried out with fresh serums obtained on the day of test (an important precaution) in 16 cases of the experimental disease. The serums tested were obtained on the 1st, 3d, 4th, 5th, 6th, 7th, 9th or 10th day after onset of fever. The twenty-four hour readings, which were considered most reliable, were negative. Plus-minus to 1 plus reactions at forty-eight hours were encountered in 6 of the patients and were not considered significant. Since the Hanger test has been found positive in malaria (therapeutic²³ and natural²⁴) and in infective hepatitis,²¹ the negative results obtained in *Phlebotomus* fever may on occasions be useful in differential diagnosis.

RECURRENCES

The fact that relapses or recurrences of the disease may occur with varying frequency during convalescence or later has been stressed by a number of careful clinical

Fig. 4.—Leukocyte counts in 100 cases of experimental *Phlebotomus* fever.

observers.²⁵ Circumstantial evidence suggested that secondary infection resulting from further *Phlebotomus* bites need not be a factor, while premature return to

23. Kopp, I., and Solomon, H. C.: Liver Function in Therapeutic Malaria, *Am. J. M. Sc.* 203: 90, 1943; unpublished data from Third (New York University) Research Service, Goldwater Memorial Hospital, New York.

strenuous physical activity was believed to favor a higher incidence of such recurrences.²⁶ During the present investigation at least 5 instances of multiple cycles of fever following a single inoculation of virus were detected among patients whose temperature was recorded for seven to eight days after defervescence

Fig. 5.—Experimental *Phlebotomus* fever in Γ. Gr., a Negro aged 50.

(fig. 7). A careful check of these patients revealed no other cause for the fever. It is noteworthy, however, that the characteristic changes in the leukocytes were not observed during the subsequent cycles of fever, even though 1 of the patients, Kne., had a low total count on two days. In patient Kal. the virus was demonstrated in the blood four days after inoculation during the first rise in temperature but not thirteen days after inoculation when his second cycle of fever began despite the fact that larger amounts were subinoculated into 2 susceptible subjects. An attempt to produce two cycles of fever by giving two inoculations of virus at an interval of three days yielded negative results in 5 subjects (fig. 2, subjects Ber., Dem., Rog., Ber. and Pri.).

DIAGNOSIS

The following attempts were made to find a specific diagnostic test, but with negative results:

1. Precipitin reaction in which the antigen was either acute stage serum or an extract of presumably infected *Phlebotomus* papatasi and the antibody consisted of convalescent serums from natural or experimental cases.

2. Complement fixation reaction in which, in addition to the antigens tried in the precipitin test, allantoic fluid and yolk sac suspensions derived from inoculated embryonated eggs were also employed.

3. Skin test utilizing fresh and heated infectious serums.

In the search for a nonspecific reaction, tests for the capacity of acute and convalescent serums to agglutinate

26. Doerr, Franz and Taussig.¹ Birt.²⁷

In localities where malaria and Phlebotomus fever occur simultaneously and when, because of the pressure of events, antimalarial therapy may be administered

in the absence of a positive smear or characteristic history, many cases of *Phlebotomus* fever are erroneously diagnosed as malaria (Birt¹⁹ and personal observations). The influence of greater familiarity with the disease and of the withholding of antimalarial therapy until the diagnosis was established by positive smear

Fig. 8—Diagnosis of *Phlebotomus* (*pappatasi*) fever in an evacuation hospital in Sicily. Influence of different use of antimalarial therapy and of increased familiarity with the disease on the incidence of diagnosis

or clinical course on the incidence of the diagnosis of *Phlebotomus* fever in an evacuation hospital in Sicily is illustrated in figure 8. The change in the number diagnosed as *Phlebotomus* fever from 1.4 per cent to 33½ per cent of all cases admitted for disease may be seen to be derived largely from the fevers diagnosed as unclassified, negative smear, malaria or fever of unknown origin.

IMMUNITY

In view of the fact that multiple attacks during the same season or in subsequent seasons are so frequently claimed, there are those who doubt that a single attack of the disease produces any appreciable immunity. It is a common experience, however, that groups which have sustained epidemics of *Phlebotomus* fever and which remain in infected areas are immune during subsequent seasons at a time when fresh groups, newly arrived in the area, are being infected. Our own investigations yielded the following information:

1. Nineteen subjects inoculated a second time with virus of proved potency at intervals of seventeen days to four months after the first experimental attack of the disease were all immune (1 tested at seventeen days, 8 at four and six weeks, 10 at four months).

2. Two physicians²⁷ residing in the United States, who gave a history of two natural attacks of the disease while in Palestine four to seven years before, were given an inoculation of the Middle East strain of the virus simultaneously with some of the aforementioned subjects. One of them developed a typical case of average severity, while the other had a mild abortive attack lasting only a few hours.

3. Complete cross immunity between the Middle East and Sicilian strains of the virus was demonstrated in

tests carried out six weeks and four months after the initial attack.

4. People recovering from so-called grip or fevers associated with inflammation of the respiratory tract were not resistant to inoculation with *Phlebotomus* fever virus in subsequent weeks.

5. Thus far tests for neutralizing antibody have been irregular. It is possible that such antibody exists only in small amounts, and further studies are necessary before an unequivocal statement can be made.

Our attempts to produce immunity without giving rise to the disease yielded the following results:

1. Persons inoculated intracutaneously or intravenously with amounts of virus too small to produce the disease were with one possible exception susceptible to reinoculation.

2. Persons who failed to develop the disease after subcutaneous or intramuscular inoculation with amounts of virus that are infective by the intracutaneous route were immune on reinoculation.

3. Although reproducible results have not yet been obtained on the inactivation of the virus by ultraviolet light, all of 11 persons who had failed to develop the disease following intracutaneous injection of virus irradiated with ultraviolet light were found to be immune on reinoculation with virus of proved potency.

PROPHYLAXIS

Although a good deal more remains to be learned about the bionomics of *Phlebotomus papatasi*, certain steps may reasonably be taken against these insects in an attempt to prevent outbreaks of the disease or to modify their course once they have developed:

1. Sleeping quarters should be on as high ground as practicable, on open, dry, sandy ground when feasible, and as far away from the native dwellings and domestic animals as possible. The more breeze in a given location the better.

2. Whenever possible the area occupied by sleeping quarters and that within a radius of 50 to 100 yards around it should be free of rubble, detritus, gardens.

Fig. 9—Protective effect of two repellents against *Phlebotomus papatasi*

vegetation and needless earthen walls or banks. The ground surfaces in such an area should be leveled and rendered as impermeable as practicable by filling in and stamping down cracks in the earth or by tarring or cementing, especially in permanent installations. Whenever that is not practical or impossible it may be worth while to attempt to render the ground unattractive for breeding by oiling with waste motor oil or crude

27. Drs. Helen Glueck and Irving Dunsky of Cincinnati volunteered for these tests.

oil or by application of creosote; sandbag walls and embankments should receive the same treatment.

3. Inside the sleeping quarters it is advisable to (a) eliminate cracks and crevices in the walls or, when that is not feasible, spray them with cresol or other available insecticide, (b) reduce all fixtures to a minimum, (c) keep bed, kits and clothing away from walls where the insects usually seek protection during the daytime, (d) use the pyrethrum bomb spray, (e) utilize electric fans to best advantage whenever available and (f) use sleeping nets of fine enough mesh (more than 45 to the inch) whenever that does not interfere with sleep.

The effectiveness of two repellents which may be applied to the exposed skin surfaces was investigated in collaboration with Drs. S. Adler and S. Arkin of the Hebrew University in Palestine. Some of the data shown in figure 9 indicate that both dimethyl phthalate and a pyrethrum vanishing cream were capable of affording considerable protection to a treated skin site for six to seven hours or longer. Tests carried out in sleeping rooms in which 150 to 200 female *Phlebotomus papatasi* flies were released indicated that both of these repellents, properly applied to all exposed surfaces, were effective during an eight hour period of sleep. Dimethyl phthalate was tested by two of us (J. R. P. and C. B. P.) during a small outbreak of *Phlebotomus* fever in the Middle East, and none of those who used it regularly at night during a five week experimental period acquired the disease. A sufficient number of those who used either nothing or a control inactive solution developed the disease in the same barracks during the same period to render the results statistically significant.

SUMMARY

1. *Phlebotomus* (pappataci or sandfly) fever is a disease of military importance because it occurs in many parts of the world where troops are stationed and because it can incapacitate large numbers of persons at a time for seven to fourteen days.

2. It occurs during the hot, dry seasons and is characterized in most instances by a fever of two, three or four days' duration, severe frontal headache, pain in the eyes, which are tender to touch and on movement, photophobia, pain in the back and extremities associated with characteristic changes in the leukocytes.

3. It is caused by a filtrable virus which is present in the blood for at least twenty-four hours before and after the onset of fever but is no longer detectable forty to forty-eight hours thereafter.

4. The virus is of small size (probably in the same range of magnitude as that of yellow fever) and, while it is readily transmissible to human beings, it has not yet been found to be infectious for any of a large variety of animals which have been tested. The virus has been preserved for at least six months in the frozen or lyophilized states.

5. The only proved vector of the disease is a small, hairy, two winged midge, *Phlebotomus papatasi*. *Aedes aegypti* and *Culex pipiens* mosquitoes and human fleas *Pulex irritans* did not transmit the disease from one human being to another in a number of tests.

6. People recovering from an experimental attack of the disease were immune to reinoculation for at least four months thereafter.

7. Two strains of virus, one isolated in the Middle East and the other in Sicily, were proved to be immunologically identical.

8. Virus irradiated by ultraviolet light has been found capable of producing immunity without giving rise to the disease.

9. Dimethyl phthalate and a pyrethrum containing vanishing cream applied to the exposed skin surfaces were both found to be effective repellents for *Phlebotomus papatasi*.

STUDIES OF BLOOD PRESSURE IN ARMY OFFICERS

OBSERVATIONS BASED ON AN ANALYSIS OF THE
MEDICAL RECORDS OF 22,741 OFFICERS OF
THE UNITED STATES ARMY

BRIGADIER GENERAL CHARLES C. HILLMAN
UNITED STATES ARMY

ROBERT L. LEVY, M.D.
NEW YORK

WILLIAM D. STROUD, M.D.
PHILADELPHIA

AND
PAUL D. WHITE, M.D.
BOSTON

During the past two years large numbers of men have been examined, under the auspices of the Selective Service System, to determine their fitness for active military duty. A recent study¹ has shown that about one fourth of those rejected for cardiovascular reasons were disqualified because of hypertension. The range of the normal blood pressure, both systolic and diastolic, is still not clearly defined; and critical levels, above which it is unsafe or unwise to accept a registrant, have not been established on a sound, factual basis. Transient, "emotional" elevations of blood pressure have been recognized but discounted by the Army. In Mobilization Regulations 1-9, issued by the War Department on Oct. 15, 1942, it is stated that, "if the blood pressure appears to be abnormally high, it will be measured after the subject has rested in the recumbent position." A cause for rejection is "a persistent blood pressure at rest above 150 mm. systolic or above 90 diastolic, unless in the opinion of the medical examiner the increased blood pressure is due to psychic reaction and not secondary to renal or other systemic disease."

At a meeting of the Subcommittee on Cardiovascular Diseases of the National Research Council, held in Washington in June 1942 and attended by representatives of the Army, the Navy, the Public Health Service, the Selective Service System and the Veterans Administration, the advisability of modifying certain of the existing criteria of physical fitness was considered. The urgent need for manpower made it imperative to recruit all eligibles who could serve with safety to them-

This is the first in a series of papers reporting these studies.

Drs. Levy, Stroud and White are members of the Subcommittee on Cardiovascular Diseases, National Research Council.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Columbia University.

Major Robert S. Gearhart, Medical Corps, United States Army, aided in guiding the work of the secretaries who transcribed the data from the original records to the special statistical forms. Miss Dorothy Kurtz, Supervisor of the Record Department of the Presbyterian Hospital, New York, directed the statistical analyses and helped in the preparation of the tables. Dr. John W. Fertig, Professor of Biostatistics, Columbia University College of Physicians and Surgeons, served as adviser in the final presentation of the material.

1. Levy, R. L.; Stroud, W. D., and White, P. D.: Report of Reexamination of 4,994 Men Disqualified for General Military Service Because of the Diagnosis of Cardiovascular Defects, *J. A. M. A.* 123: 937 (Dec. 11), 1029 (Dec. 18) 1943.

selves and with advantage to the armed forces. With respect to the upper limits of blood pressure, it was suggested by some that these might be raised, whereas others claimed that the existing levels were too high. As a result of the discussion, it became clear that a change in either direction was not justified on the basis of the evidence at hand; for there was no large series of observations carried out over long periods of time.² To obtain the lacking information as quickly as possible seemed highly desirable.³

It was known that, in the Office of the Surgeon General of the Army, there were filed abstracts of the medical records of some 23,000 officers, on which were noted the results of annual physical examinations made between January 1924 and December 1941. Appended to many of these were the detailed reports of special examining boards, submitted on the occasion of promotion or retirement or of examination incident to hospitalization. Often electrocardiograms and teleroentgenograms were made at such times, and other laboratory procedures were employed. In many cases the record began with the admission of the young man, as a cadet, to West Point. Annual examinations were discontinued in 1941 owing to the pressure of work essential to the war. No examinations were made after an officer had retired unless he applied for reinstatement for active duty. Samples of these records were inspected, and it was at once apparent that here was a valuable storehouse of material.

To supplement the histories in the Surgeon General's Office, Col. Albert G. Love, Medical Corps, United States Army, kindly offered to place at our disposal his notes on the medical records of 5,000 officers who were in the service on Jan. 1, 1901 and also those commissioned between that time and Dec. 31, 1916. These had been analyzed, in collaboration with Professor Lowell J. Reed of the Johns Hopkins University, and the results published in 1931 and 1932 in a series of papers dealing with "Biometric Studies on U. S. Army Officers." It seemed probable that the use of these earlier notes, particularly those pertaining to blood pressure, might lengthen the period of observation in some of the cases included in the larger series. Reference to the conclusions of Reed and Love will be made in appropriate places.

The availability of this material appeared to offer an unusual opportunity to study variations of blood pressure during the passage of a number of years and to relate them to various other factors. Of particular immediate importance was the significance of transient hypertension. Additional topics for consideration which at once came to mind were the later course of those who developed sustained hypertension, the relationship between body weight and hypertension, and the significance of tachycardia, both transient and sustained. These could all be correlated with disability retirement and mortality rates at various ages, with the causes of retirement and death and, in those who died, with the findings at necropsy.

It was realized that the type of subjects studied imposed certain limitations on the universal applicability of the results of the analysis. All were men, they

represented a group originally selected because they were physically qualified according to certain rigid standards, and they lived under the special conditions of military service, both at home and in the field. However, it should be stressed that the primary aim of this investigation was to obtain information useful to the

50 to 54 years	684	3.0

Army; of secondary importance, though of equal interest, was the desire to contribute to the general knowledge of the problems involved.

PLAN OF PROCEDURE

On Sept. 12, 1942 a contract, recommended by the Committee on Medical Research, was made between the Office of Scientific Research and Development and Columbia University, providing funds for this study. Dr. Levy was appointed chairman of the project.

A statistical form was devised for recording the necessary data. Ten secretaries with special qualifications for the task were chosen and installed in a room in the Office of the Surgeon General. It was necessary that the clerical work be carried out there, since the records were in daily use. The information contained in each officer's medical folder was transcribed by the secretaries to a statistical sheet. Each clerk was given a typed set of directions containing definitions of the terms employed and criteria for the diagnoses. These criteria will be cited where they apply to the topics under discussion.

The completed forms were shipped to the Record Room of the Presbyterian Hospital in New York, where the data were transferred to punch cards. The final statistical analyses were then made by machine.

GENERAL ANALYSIS OF MATERIAL

A total of 22,741 records proved to be suitable for study. In 1,821 of these supplemental information was obtained from Colonel Love's notes made prior to 1924. In some instances the final status of an officer was learned by reference to the 1943 edition of the Official Army Register. Original necropsy protocols were reviewed at the Army Medical Museum through the courtesy of Col. J. E. Ash, its director.

Status at Time of Study (table 1).—Of the total number of 22,741 men, 70 per cent were on active duty when the data were assembled, 17 per cent were

2. Statistics of life insurance companies are based largely on mortality experience following a single blood pressure reading and apply only in limited fashion to certain aspects of the present analysis.

3. A tentative plan of study was submitted at the meeting by Dr. E. V. Allen, member of the Subcommittee on Cardiovascular Diseases, National Research Council, and Dr. E. A. Hines Jr. of the Mayo Clinic. This was modified materially with respect to both scope and procedure as the project matured.

retired and still living and 10 per cent were dead. Of the 2,292 who had died, an autopsy report was available in 639 (28 per cent). In only 2 per cent of the total number (448 cases) was the status unknown because the officer had left the service and could not be traced.

Age Distribution at First Examination (table 2).—The largest number of men, 8,252, or 36 per cent, were under 25 years of age and the numbers decreased progressively in the succeeding five year periods. Fifty-six per cent were under 30 years of age and 73 per cent were under 35 when first examined.

Length of Service at First Examination (table 3).—It has been customary for the War Department to file all reports of physical examination of officers in the Adjutant General's Office with other personnel records. In order to have this medical information more readily available for current use, the practice was begun in 1924 of transcribing essential data to cards filed in the Surgeon General's Office. The present series of studies is based largely on the data found on these cards. Since it has been impracticable for the Surgeon General's Office to review and abstract all officers' personnel records in the War Department, the records of officers already in the service in 1924 are incomplete. In 41 per cent of the total number of cases there was a report of medical examination during the first year of service. In 27 per cent the officer's physical condition was first recorded after he had been in the Army from five to nine years, and in 5 per cent no record was available until after twenty to twenty-four years of service.

Length of Observation Period (table 4).—A small number, 821, or 4 per cent of the total, were given only

TABLE 3.—Length of Service at First Examination

	Number	Per Cent

25 years or over.....	414	1.8

a single examination. Seventy-two per cent were under observation from five to nineteen years, and 38 per cent (8,671) were observed from fifteen to nineteen years. In 1,437 cases, or 6 per cent of the total, the observation period was twenty years or over.

Distribution by Branch of Service (table 5).—Of the total number, 11 per cent (2,465) were transferred from one service to another during the period of obser-

vation, so that they were listed under more than one branch. The sum of the percentages, therefore, exceeds 100. However, the general distribution trend is evident.

Twenty-nine per cent were in the infantry, 13 per cent were in the air corps, 12 per cent were in the field artillery and 11 per cent were in the medical corps.

Major general.....	21	0.1
Lieutenant general.....
Not specified.....	2	0.0

The coast artillery, cavalry and quartermaster corps followed in this order. There were only 5 per cent in the engineers. Those whose work was of a sedentary character have been grouped together; they comprised less than 3 per cent of the total. In 8 per cent the branch of service was not specified.

Rank at First Examination (table 6).—As might have been anticipated, the largest number, 5,368, or 24 per cent, were second lieutenants when first examined. Next in order were West Point cadets 20 per cent, first lieutenants 19 per cent and captains 18 per cent. Seven per cent were warrant officers and 7 per cent were majors. Comparatively few, only 4 per cent, received their first examination as lieutenant colonels or when they had attained higher rank.

COMMENT

There is need for studies of blood pressure in persons observed over long periods of time. The reports of annual medical examinations of army officers afford suitable material, although it is recognized that they concern a selected group of male subjects. An analysis of 22,741 of these records has been undertaken. The purposes of the study, sources of the records, plan of procedure and a general survey of the material have been given; in subsequent papers various aspects of the work will be discussed in detail.

METHYL BROMIDE POISONING

WITH SPECIAL REFERENCE TO NERVOUS SYSTEM
MANIFESTATIONS

RUSSELL N. DeJONG, M.D.

ANN ARBOR, MICH.

Methyl bromide has been used extensively during recent years, first as a refrigerant, later as a fumigant and recently as a delousing agent. It is an insecticide of great effectiveness and wide application and is capable of protecting a wide variety of foods, shrubs, plants, grains and textiles. Its use is recommended by entomologists in the solving of insect control problems for many reasons: It leaves no residual odor or taste; it is convenient to handle and its fumes do not constitute a fire or explosion hazard when mixed with air under ordinary conditions of use; it is highly toxic to insects in all stages of development; it has a low absorption and high penetrating power; it is low in cost. There is increased interest in the use of methyl bromide at the present time as it has been found to be very effective in the extermination of lice and bedbugs, and it is being used for this purpose in the armed forces. The War Production Board has recently announced that it has been placed under allocation.¹

Methyl bromide (CH_3Br) is a colorless, odorless gas at ordinary temperatures and pressures. It has a specific gravity of 1.732 at 0 C., a molecular weight of 94.94, a melting point of -93 C. and a boiling point of 4.5 C. At ordinary temperatures it is approximately 3.3 times as heavy as air. It is soluble in most common organic solvents but is only slightly soluble in water. It has high chemical stability. In manufacturing it is compressed and put into containers as a liquid and can be withdrawn as a liquid which immediately vaporizes. It is known to be toxic to human beings if its vapors are inhaled, and the Division of Industrial Hygiene, National Institute of Health, United States Public Health Service, has advised the following precautionary measures: avoidance of breathing the gas; thorough ventilation of cars, rooms or buildings on completion of fumigation; the use of a gas mask or positive pressure hose when exposure is necessary; avoidance of spillage with removal of clothing that has become impregnated; care in storage. Manufacturers are also aware of the toxicity of methyl bromide, and care is used in the preparation and utilization of the substance.

The toxic effects of methyl bromide are well known. In experimental animals it has been found to be the most toxic, both in high concentration and short exposure, and in low concentration and long exposure, of four organic halides—methyl bromide, methyl chloride, ethyl bromide and ethyl chloride.² Irish, Adams, Spencer and Rowe³ found that warm blooded animals can survive fairly high concentrations for brief periods of time, but longer exposure leads to pulmonary irritation with congestion and edema, often developing into

typical confluent bronchopneumonia. Lower concentrations with prolonged exposure result in excitability, muscular tremors and even paralysis, from which the animals can recover completely when removed from the gas. Sayers, Yant, Thomas and Berger² found that animals exposed to methyl bromide developed respiratory difficulty, irritability, unsteadiness, excitement and convulsions. Pathologically these animals, showed degeneration of the heart muscle, congestion and hemorrhage of the lungs, and congestion of the kidneys, spleen and liver. The brain and meninges also were congested. These changes were more apparent after long exposure to low concentrations than after brief exposure to high concentrations.

While there is little information regarding the level of response to methyl bromide vapor in human beings, it is known from animal experiments that care must be used in handling the substance.³ Cases of methyl bromide poisoning in human beings have been reported, some with fatal termination, but most reports are from the foreign literature and the conditions of exposure are not adequately described. The paucity of reports of methyl bromide intoxication in this country may be due to the precautions used in manufacturing and dispensing it, although in the past the substance has not been in as great use in this country as in Europe. Jaquet⁴ in 1901 reported 1 case with vertigo, weakness and temporary visual disturbances following a brief exposure, and 2 cases with similar symptoms plus asthenia and psychic disturbances following longer exposure. Steiger⁵ in 1918 reported 1 case with delayed nervous system symptoms. A case with prostration and apathy with a history of repeated poisonings was reported by Cade and Mazel⁶ in 1923 and a fatal case by Glaser⁷ in 1928. In all some 42 cases have been reported, of which 12 proved fatal, 23 were reported as recovered, and in 7 the information is incomplete.⁸ Symptoms referable to the nervous system appear to be typical for methyl bromide poisoning. They vary from individual to individual but are manifest as headache, vertigo, pareses or paralyses, visual disturbances, delirium, psychic disturbances and even convulsions and coma. There may be some individual predisposition. Acute poisoning usually results in pulmonary irritation leading to bronchial pneumonia. Watrous⁹ in 1942 made a study of 90 persons who worked with methyl bromide in a filling and sealing room during a two weeks period. Here the concentration of the vapor was less than 35 parts per million of air, a concentration well in the range that is considered to be "safe." He found localized and mild systemic toxic effects in 31 persons. Anorexia, nausea and vomiting were seen most frequently, then headache, vertigo, difficulty in focusing the eyes, lethargy, gastrointestinal symptoms, muscular pains, faintness and dimness of vision. He also noticed a characteristic vesicular burn, resembling a second degree burn, that occurred when liquid methyl bromide came in direct contact with the skin, and a late itching dermatitis that resulted from contact.

Methyl bromide is less toxic than some fumigants and insecticides, but it does present a definite toxic hazard, especially as it does possess sufficient warning properties to prevent serious voluntary exposure. Careful precautions are used in its manufacture, storage and use in this country. The following 2 case reports indicate, however, that complications may arise even when such precautions are used:

REPORT OF CASES

CASE 1.—History.—R. L. E., a youth aged 17, complained of dizziness and of numbness and stiffness of the feet and legs. He had worked as a "canner" of methyl bromide for six months before onset of his present symptoms. The gas was liquefied at -22°F . (-30°C .) and put into cans. Scattered gas was removed by a suction flow. It was stated that he had worked longer as a canner than any other employee and had lost 20 pounds (9 Kg.) during this time. He gave a history of having received numerous methyl bromide blisters on his hands. In November 1943 he began to notice mild vertigo and unsteadiness of vision (oscillopsia), which were more or less constant but not severe enough to incapacitate him for his work. About ten days later he noticed numbness and tingling of the soles of the feet, which later ascended the legs as far as the groin. With the paresthesias he noted some stiffness and weakness of the lower extremities, with disability in walking and running. There were no difficulties with the use of the upper extremities. The vertigo disappeared after about three weeks, but the paresthesias and stiffness of the legs persisted. The patient was put to bed the latter part of November, about three weeks after the onset of the symptoms, because he had developed a tachycardia. This improved with rest and the weakness of the legs became less, although the paresthesias persisted.

Examination.—The patient was a slender young man of fair physical development. The temperature, pulse and respirations were normal, and blood pressure was 104/80. He was intelligent and cooperative. There was a slight swaying in his gait, and the Romberg sign was present. The pupils were moderately dilated but reacted normally. The extraocular movements and the optic fundi were normal. There was nystagmus on lateral gaze. The biceps and triceps reflexes were active and equal. There was no Hoffman's sign. There was a moderate amount of dysidiadokokinesia bilaterally, and there was slight intention tremor on the finger to nose test. The abdominal and cremasteric reflexes were active. The patellar and achilles reflexes were exaggerated. There were abortive ankle clonus and a positive Babinski sign bilaterally. There was mild ataxia on the heel-to-knee-to-toe test bilaterally. Vibratory sense was slightly diminished in the lower extremities. Position and cutaneous sensations were normal, and there was no astereognosis. Examination of the blood showed the hemoglobin to be 97 per cent, red blood cells 4,800,000 per cubic millimeter, white blood cells 17,250 per cubic millimeter, with 84 per cent polymorphonuclear cells, 9 per cent large lymphocytes and 7 per cent small lymphocytes. The platelets were normal in number. The white blood cells showed a moderate toxic granulation, but no abnormal cells were seen. The blood bromide determination was 13 mg. of sodium bromide per hundred cubic centimeters. The Kahn reaction on the blood was negative. Spinal puncture showed a pressure of 150 mm. of water without block. The Kahn reaction and the colloidal gold and mastic curves were entirely negative. There were no cells. The total protein was 22 mg. per hundred cubic centimeters.

Course.—The patient was treated symptomatically and was advised against returning to his previous employment. One month later he reported progressive improvement with gain in appetite and weight and disappearance of staggering and numbness. He still noted pronounced ease of fatigue.

CASE 2.—History.—I. S., a man aged 26, complained of weakness of the legs and difficulty in walking. He had been employed for several months in the distilling of methyl bromide. Three weeks before admission, after working for about four hours at his machine, he became weak and dizzy. He was taken to the first aid department, where he stayed all night, and he had some nausea and vomiting during the night. He returned to his work two days later and at this time again

became dizzy and weak and noticed unsteadiness and double vision. There was also numbness and tingling of the legs and arms, which was followed by extreme weakness; his gait became ataxic and he dropped objects from his hands without realizing it. The weakness of the arms disappeared within a few days, but the weakness of the legs persisted. The patient was forced to stop his work two weeks later because of difficulty in walking. He had noticed drowsiness, a decided loss of appetite and loss of 15 pounds (7 Kg.) in weight in one month. A few days after the development of the patient's symptoms a leak was said to have been discovered in the apparatus with which he was working.

Examination.—The patient was well developed and did not appear to be acutely ill. He responded slowly to questioning. Temperature, pulse and respirations were normal; blood pressure was 114/70. His gait was weak and unsteady, and he walked with a wide base, took short steps, and his feet slapped the floor in walking. He was unable to walk tandem. The Romberg sign was present. The pupils were moderately dilated. The extraocular movements and the optic fundi were normal. There was nystagmus on extremes of lateral gaze. The biceps and triceps reflexes were normal. There was slight incoordination and intention tremor in the upper extremities. The abdominal and cremasteric reflexes were normal. The patellar reflexes were exaggerated, but the achilles reflexes were diminished. Vibratory sense was diminished at the ankles. Position sense was normal. Cutaneous sensations were diminished in both lower extremities, with a stocking distribution extending to the knees. Deep pain sensation was present. There was no astereognosis. Laboratory tests showed a negative Kahn reaction on the blood. The skull roentgenogram was negative. Blood bromide determination was 9 mg. of sodium bromide per hundred cubic centimeters. Spinal puncture showed normal pressure without block; there were 3 cells per cubic millimeter; the Kahn, colloidal gold and mastic tests were negative, and the total protein was 48 mg. per hundred cubic centimeters. Urinalysis was normal. Blood count showed a hemoglobin of 90 per cent, red blood cells 4,700,000 per cubic millimeter and white blood cells 9,000 per cubic millimeter, with 63 per cent polymorphonuclear cells, 30 per cent lymphocytes, 5 per cent monocytes and 2 per cent eosinophils. A psychometric determination awarded the patient an intelligence quotient of 85, placing him in the low average group.

Course.—The patient's symptoms improved progressively during a two weeks period of hospitalization. His gait improved, and he complained less of the paresthesias and of the weakness. Two months later he still noted some weakness and paresthesias, however, with some residual blurring of vision. He had returned to his work two weeks after discharge from the hospital but had frequently lost time from work because of his symptoms.

CASE 3.—As this report goes to press, a third patient with nervous system manifestations resulting from methyl bromide intoxication has been observed. This man, aged 43, an assistant operator in the manufacture of methyl bromide since Nov. 7, 1943, noticed the onset of tinnitus about Jan. 15, 1944. This was followed by weakness and numbness of the legs, staggering gait, vertigo and headaches. A few days later he noted weakness of the left arm and leg, blurring of vision and lethargy. He was forced to stop his work on January 22. Beginning the middle of February he noted some improvement, although the drowsiness was followed by insomnia and he had had one attack of nausea and vomiting. When examined on May 5, 1944 he showed anisocoria, an ataxic gait, exaggerated tendon reflexes especially on the left, abortive ankle clonus, and diminished vibratory sensibility in the lower extremities.

SUMMARY

Methyl bromide is a toxic substance, and nervous system or other complications may arise from exposure to it. Recent allocation of methyl bromide by the War Production Board for use in the armed forces merits extreme care in its disposition and utilization. While it can be handled without injury if used intelligently, its toxic potentialities must be borne in mind, and its indiscriminate and careless use must be avoided.

PRODUCTION OF POTENT INACTIVATED VACCINES WITH ULTRAVIOLET IRRADIATION

III. AN ABBREVIATED PRELIMINARY REPORT ON A COMPLETELY INACTIVATED POLIOMYELITIS VACCINE (LANSING STRAIN VIRUS) IN MICE

ALBERT MILZER, PH.D.
FRANZ OPPENHEIMER, PH.D.
AND
SIDNEY O. LEVINSON, M.D.
CHICAGO

A new method and equipment for the preparation of potent vaccines completely inactivated by ultraviolet irradiation of continuously flowing thin (less than 1 mm.) films of turbid suspensions of bacteria and viruses for less than one second has been described.¹ We have reported² the preparation of highly antigenic, completely inactivated vaccines for rabies and St. Louis encephalitis viruses with this technic. The present paper is a preliminary report on the preparation and antigenic studies of a completely inactivated vaccine prepared from the mouse adapted Lansing strain of poliomyelitis virus which not only evokes the formation of specific neutralizing antibodies in immunized mice but also confers a high degree of protection against subsequent intracerebral inoculation. The complete details of this paper will be published elsewhere.

Although there are a few publications³ of the effectiveness of ultraviolet irradiation in destroying the poliomyelitis virus, to our knowledge no one has made antigenicity studies of irradiated poliomyelitis vaccines. It has been shown repeatedly that monkeys vaccinated with various completely inactivated poliomyelitis virus preparations develop little or no immunity, while active virus vaccines may stimulate immunity but are too dangerous for human use.⁴ Recently the development of both resistance to intracerebral inoculation and potent humoral antibodies against the Lansing strain in mice immunized with active virus has been reported,⁵ but no attempts were made to vaccinate mice or cotton rats with completely inactivated preparations of this strain.

From the Samuel Deutsch Serum Center of Michael Reese Hospital and the Michael Reese Research Foundation.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Michael Reese Research Foundation. This work is a parallel development with other research in poliomyelitis supported by the National Foundation for Infantile Paralysis at Michael Reese Hospital. Supported in part by Parke, Davis & Co.

EXPERIMENTAL

Swiss mice of a single strain, 4 to 5 weeks of age, were used. Virus suspensions were prepared from pooled brains and cords of mice paralyzed two to five days after intracerebral inoculation of the mouse adapted Lansing strain of poliomyelitis virus⁶ and stored at -76 C. Four per cent uncentrifuged, pooled poliomyelitis virus suspensions were completely inactivated by our technic of ultraviolet irradiation in an exposure time of 0.5 to 0.66 second. Four separate lots of completely inactivated, irradiated vaccines were prepared and tested for immunizing potency. Each lot of irradiated vaccine was shown to be completely inactivated by (1) repeated intracerebral inoculations in both mice and monkeys,⁷ (2) adjusting the vaccine suspension to

7. Shaughnessy, H. J.; Harmon, P. H., and Levinson, S. O. The Resistance of the Virus of Poliomyelitis to Ultraviolet Irradiation. *Proc. Soc. Exper. Biol. & Med.* 4:14-16 (March) 1930. Levinson, S. O. Accelerated Inactivation of Poliomyelitis. *Science* 74:520-521 (Nov. 23) 1931.

8. Harmon, W. M., and Levinson, S. O. Neutralizing Activity of Poliomyelitis Virus. Effect of pH on the Activity of the Virus. *Proc. Soc. Exper. Biol. & Med.* 1942, 23, 343.

The presence of neutralizing antibodies against the Lansing strain of poliomyelitis virus in undiluted, pooled serums obtained from selected vaccinated mice was demonstrated as early as one week after a single dose of vaccine. One week after the second and third doses of vaccine the antibody titer had increased at least tenfold. The neutralization test employed was a slight modification of the technic described by Haas and Armstrong.⁹ At least 8 mice were inoculated with each serum-virus mixture, and positive and negative controls were included in every test. Table 2 shows the results of titrations of two positive serums in which serial dilutions of serum in buffered saline (p_H 7.4) were mixed with an equal volume of 10 per cent virus suspension.

Additional experiments which have been completed show that the irradiated poliomyelitis vaccine can be stored as long as four and a half months at 3 C. without significant loss of immunogenic potency. A rhesus monkey injected subcutaneously with three doses of irradiated vaccine (0.5, 1 and 1 cc. at weekly intervals) developed neutralizing antibodies one week after the second and third doses of vaccine. No antibodies were detected in serum drawn before vaccination or one week after the first injection.

SUMMARY AND CONCLUSIONS

1. Several separate lots of completely inactivated poliomyelitis vaccine (Lansing strain) were prepared by means of a new technic of ultraviolet irradiation. The virus was consistently inactivated in less than one second exposure to the source of irradiation.

2. The irradiated poliomyelitis vaccines were proved to be completely inactivated by critical safety tests in mice and monkeys.

3. Mice immunized with three doses of the irradiated poliomyelitis vaccine developed significant resistance to intracerebral inoculation and also specific serum neutralizing antibodies.

4. The irradiated poliomyelitis vaccine exhibited no significant loss of potency after four and a half months storage at 3 C.

Babylonian-Assyrian Medicine.—The existence of a well established medical profession in that broad expanse between the Euphrates and the Tigris rivers was revealed by the discovery of the so-called Code Hammurapi. According to most Assyriologists, Hammurapi was the sixth king of the first dynasty of Babylonia, reigning for fifty-five years, around 725 B. C. He was a stern but just ruler and a great soldier; he codified the existing customs and laws regulating the social and commercial conduct of his subjects, mainly with the purpose of defending the weak against the oppression of the strong. Among the two hundred and eighty-two separate regulations, nine refer to the practice of surgery—to the medico-legal phase of medicine. The fees were fixed according to the social strata of the patients, and rather severe penalties were meted out in cases of operative failure. Singularly enough, no references are found pertaining to nonsurgical diseases; probably that phase of medicine was in the hands of priests, and cures depended on incantations and prayers more than on drugs. Yet we must not lose sight of the fact that they had a not inconsiderable knowledge of chemistry, which may have been a factor in the preparation of drugs.—Ricci, James C.: *The Genealogy of Gynaecology*, Philadelphia, Blakiston Company, 1943.

Clinical Notes, Suggestions and New Instruments

INTRAVENTRICULAR PENICILLIN IN THE TREATMENT OF STAPHYLOCOCCIC MENINGITIS

CAPTAIN WILLIAM S. McCUNE AND CAPTAIN JACK M. EVANS
MEDICAL CORPS, ARMY OF THE UNITED STATES

Several reports have appeared in the literature of the use of penicillin intrathecally, with good results. Rammelkamp and Keefer¹ treated 6 patients with intrathecal penicillin, including 2 with brain abscess and meningitis and 2 with meningitis. In 2 of the patients who died, penicillin was demonstrated in the cerebrospinal fluid removed from the third ventricle and from the cisterna magna. They suggested an initial dose of not more than 10,000 Florey units, followed by subsequent doses of 5,000 units every twenty to twenty-four hours. Absorption and excretion were more rapid in patients with meningitis than in those without meningitis. There were no reactions to the intrathecal penicillin except as evidenced by an increase in the number of leukocytes in the spinal fluid and an occasional headache.

A discussion arising from the death of a patient with streptococcic meningitis who had been treated with penicillin intrathecally produced the suggestion by Lieut. Col. R. G. Spurling of the neurosurgical service that the drug might not be reaching

the injection within the ventricles in sufficient concentration. In the case to be reported, after the clinical course had reached a standstill under intrathecal administration, it was decided to inject the chemotherapeutic agent directly into the ventricles to insure maximum levels within the brain.

A brief survey of the literature reveals no reported cases of this method of penicillin administration. It is thought noteworthy that in this case the intraventricular injection of the drug was effective and produced no apparent harmful reaction. It should be emphasized that this method of treatment is recommended only for those patients who have failed to respond to intraspinal penicillin therapy.

REPORT OF CASE

A sergeant aged 25 had been well and free from symptoms until the evening of June 12, 1943. At that time, while riding a bicycle along a highway near Minersville, Pa., he was struck by an automobile and rendered unconscious.

He was taken to the Pottsville Hospital, where physical examination is said to have revealed an irregular swelling on the right forehead, pupils which were equal, dilated and reacted poorly to light, and an abrasion on the left shoulder. The temperature was 99.4 F. Physical and neurologic examination except for moderately deep unconsciousness were otherwise negative.

Blood studies were within normal limits. X-ray films of the skull showed a linear fracture in the right frontal bone starting 1 cm. from the midline and extending into the right frontal accessory nasal sinus.

From the Neurosurgical Section and the Laboratory Section, Walter Reed General Hospital, Washington, D. C.

1. Rammelkamp, C. H., and Keefer, C. S.: The Absorption, Excretion and Toxicity of Penicillin Administered by Intrathecal Injection, *Am. J. M. Sc.* 205: 342 (March) 1943.

Throughout the following two weeks the patient remained semiconscious, irrational, restless and incontinent of urine. He was said to have recognized his wife on one occasion. Temperatures varied from normal to 102.4 F. (axillary), pulse rates from 72 to 102. Lumbar puncture was said to have revealed blood tinged spinal fluid under a pressure of 330 cm. of water on June 23. The neurologic findings did not change materially from day to day. Treatment included only routine nursing care, 50 per cent dextrose twice daily and sulfathiazole 1 Gm. every four hours for two days. He was transferred to Walter Reed General Hospital on June 26.

On arrival at this hospital he was unconscious, restless and uncooperative, and remained so throughout the following six days. The temperature on arrival was 103 F. (rectal) and soon rose to 105, the pulse rate 128, respiratory rate 24. Neurologic examination was negative except for moderate rigidity of the neck, a positive Kernig sign, absent abdominal reflexes and positive Babinski and Gordon signs on the right.

A spinal puncture yielded cloudy fluid with an initial pressure of 180 cm. of water. Dynamics were normal. The fluid contained 23,750 leukocytes and 90 per cent polymorphonuclears. Cultures showed coagulase positive *Staphylococcus aureus*. The

holes in the posterior parietal area were made, but no collection of epidural fluid or pus was found. A needle was then passed into the right ventricle and 8 cc. of slightly turbid, colorless fluid withdrawn, which showed only minimal bacteriostatic activity in spite of the fact that 7,500 units of penicillin had been introduced by lumbar puncture two hours earlier. Seven thousand five hundred Florey units of penicillin was then dissolved in 5 cc. of saline solution and introduced into the ventricle. The galea and skin were closed. There was no immediate reaction to the procedure. On the following day, July 6, the temperature had fallen to 101 F. and the pulse rate to 80. On July 7 the temperature rose again to 103 F., the pulse rate to 104. Spinal tap resulted in fluid which was much clearer and contained only 675 leukocytes, with 65 per cent polymorphonuclears. The culture of this fluid was sterile. The right ventricular fluid removed contained only 170 leukocytes, with 59 per cent polymorphonuclears. The temperature on the following day was 101 F. but thereafter was never higher than 100.4 F.

Because of the shortage of the therapeutic agent, penicillin was stopped on July 7 and sodium sulfadiazine begun with an initial intravenous dose of 5 Gm., followed by 2.5 Gm. every

twelve hours until July 11. From July 11 to July 18, 4 Gm. of sulfadiazine was given daily by mouth, and on July 18 all medication was stopped. After the withdrawal of penicillin and the change to sulfadiazine the spinal fluid cell count rose to 345 cells on July 10 and 665 cells on July 12 but then gradually fell to a count of 17 cells with 4 per cent polymorphonuclears on July 26. On that day, through a right frontal burr hole exploration, a small, old, subdural hygroma containing about 14 cc. of clear, yellow, sterile fluid was evacuated.

During this course of treatment the patient's mental state gradually improved to a level at which he was able to recognize friends, eat with help, read large type and carry on a very simple conversation. At last report he was able to play rummy, read the comic strips and go to the bathroom with help. The meningitis has been

cured. After July 14 his temperature remained normal and neurologic examination showed no abnormal findings. There were no pronounced changes in the urine or blood counts during treatment.

SUMMARY AND CONCLUSIONS

This case of staphylococcal meningitis treated with intrathecal and intraventricular penicillin is presented chiefly to show that intraventricular use of penicillin as an adjunct to the intrathecal route of administration is possible without untoward reactions and with good effect. The fact that there was evidence of only minimal passage of penicillin from the spinal canal into the ventricles in two hours reemphasizes the fact that the normal flow of cerebrospinal fluid may hinder the free passage of therapeutic agents from the spinal canal into the ventricular system. This is especially true in meningitis when arachnoid adhesions and exudate may partially obstruct the normal spinal fluid pathways. The introduction of penicillin directly into the ventricles overcomes this handicap and insures a more uniform distribution of the therapeutic agent throughout the cerebrospinal fluid system. The dosage used in this case was not large and in the light of future knowledge may prove to have been too small. The levels of penicillin in the spinal fluid during treatment are shown on the graphic chart. The introduction of a needle into the ventricle in the acute stage of meningitis should be performed with caution, and not until penicillin has been given intraspinally for several days.

white blood cell count was 9,200, red blood cell count 4,000,000, hemoglobin 94 per cent, and nonprotein nitrogen 25 mg., blood sugar 101 mg. and chlorides 495 mg. per hundred cubic centimeters. The urine had a specific gravity of 1.011, no albumin, no sugar and a normal sediment. An electroencephalogram showed the dominant rhythm to be slow, but there was no evidence of focalization.

Treatment and Course.—On admission sodium sulfadiazine 5 Gm. was administered intravenously, followed by 2.5 Gm. every twelve hours for two days. On June 28, however, the temperature was still 103.8 F. (rectal) and the pulse rate 118. Spinal tap showed an initial pressure of 210 cm. of water with cloudy fluid containing 6,480 leukocytes, 90 per cent polymorphonuclears and a positive culture for *Staphylococcus aureus*. Consequently, intrathecal penicillin was begun, with an initial dose of 10,000 Florey units. This was followed by subsequent doses of 7,500 units intrathecally twice daily for three doses, then 5,000 units twice daily for five days. No untoward reactions were noted. The state of unconsciousness remained unchanged, but the temperature dropped to 101.4 F. and the pulse rate to 92. The number of leukocytes in the spinal fluid dropped to 2,200 on June 30 and the culture became sterile. However, the spinal fluid cell count fell only slightly beyond that point, and on July 5, after seven days of intrathecal penicillin, the temperature rose to 102 F. In view of the possibility of an epidural abscess of the brain, bilateral burr

COUNCIL ON PHARMACY AND CHEMISTRY

At periodic intervals the Council on Pharmacy and Chemistry will offer brief statements on the present status of therapeutic or prophylactic procedure in fields of current interest. This information will be selected for its special value to those engaged in general practice.

ADMINISTRATION

Method of Preparing Penicillin for Treatment

Penicillin is supplied in ampuls of different sizes—25,000 units and 100,000 units each. As penicillin is extremely soluble, it may be dissolved in small amounts of sterile distilled, pyrogen-free water or in sterile isotonic solution of sodium chloride. When large unit sizes are being used in hospitals, the contents of the ampul should be dissolved in water or saline solution so that the final concentration is 5,000 units per cubic centimeter. This solution should be stored under aseptic precautions in the ice box and made up fresh every day. Solutions for local or parenteral use may be diluted further, depending on the concentration desired.

For intravenous injection

1. The dry powder may be dissolved in sterile isotonic solution of sodium chloride in concentrations of 1,000 to 5,000 units per cubic centimeter for direct injection through a syringe.

2. The dry powder may be dissolved in sterile saline or 5 per cent dextrose solution in lower dilution (25 to 50 units per cubic centimeter) for constant intravenous therapy.

For intramuscular injection

1. The total volume of individual injections should be small, i. e. 5,000 units per cubic centimeter of isotonic saline solution.

For topical application

1. The powdered form of the sodium salt is irritating to wound surfaces and should not be used.

2. Solutions in isotonic salt solution with a concentration of 250 units per cubic centimeter are satisfactory. For resistant or more intense infections this concentration may be increased, to 500 units per cubic centimeter.

DOSAGE

The dosage of penicillin will vary from one patient to another, depending on the type and severity of infection. Recovery has followed in many serious infections following 40,000 to 50,000 Oxford units a day; in others 100,000 to 120,000 or even more is necessary. The objective in every case is to bring the infection under control as quickly as possible. It is well to remember that penicillin is excreted rapidly in the urine, so that following a single injection it is often impossible to detect it

in the blood for a period longer than two to four hours. It is well, therefore, to use repeated intramuscular or intravenous injections every three or four hours or to administer it as a continuous infusion.

In the treatment of *meningitis*, *empyema* and *surface burns of limited extent*, penicillin should be injected directly into the subarachnoid space, into the pleural cavity, or applied locally in solution containing 250 units per cubic centimeter.

SATURDAY, JULY 8, 1944

TIME NOW TO PROTEST AGAINST GOVERNMENT'S THREAT TO MEDICAL EDUCATION

In January 1944 it seemed that civilian and military needs for doctors would be met reasonably satisfactorily by the arrangement in which the 55 per cent of entering medical school classes would be provided by the Army Specialized Training Program, 25 per cent by the Navy V-12 Program and 20 per cent from civilian sources. In the past six months this program has rapidly deteriorated. Today medical educators and the medical profession of the country refuse to accept the responsibility for the acute shortage of medical care which will threaten this country within a few years if current regulations and policies persist. The responsibility must rest with the armed forces, the Selective Service System, the President and the Congress of the United States.

In February the Army drastically curtailed the Army Specialized Training Program and has since renegotiated its contracts with medical schools to provide 28 per cent of the 1945 entering classes instead of 55 per cent, increasing to 47 per cent the numbers medical schools must obtain from civilian sources.

In April the Selective Service System abolished all further occupational deferments of premedical and medical students not enrolled in medical schools by July 1, 1944. As a consequence, it was estimated that the entering classes of 1945 would be reduced 25 to 30 per cent.

The threat to medical care entailed in these policies was pointed out to General Hershey, the Secretaries of War and the Navy, the President and others, with the suggestions that the situation could be met by (a) reinstitution of the inactive reserves by the Army and Navy, which functioned well for a year, and/or (b) an

appropriate Selective Service adjustment, which was definitely a second best arrangement.

The Army and Navy rejected the first alternative as an evasion of the Selective Service law, and the Selective Service System rejected the alternate proposal because of the acute need of the Army for young men. The needs for medical care were considered to be subordinate to the needs of the fighting forces.

Alarmed at these developments, the House of Delegates of the American Medical Association, on the recommendation of the Council on Medical Education and Hospitals of the American Medical Association, passed the following resolution at its opening session, June 12:

WHEREAS, The present policy of the Army and the Selective Service System in preventing the enrolment of a sufficient number of qualified medical students will inevitably result in an overall shortage of qualified physicians, with imminent danger to the health and well being of our citizens; therefore be it

Resolved, That it is imperative that immediate action be taken by the President or the Congress of the United States to correct the current drastic regulations, which result in a restriction of the number of students qualified to enter the courses of medical instruction in approved medical schools.

This resolution was sent to the President, the Secretaries of War and the Navy, the Selective Service System and all members of the House and Senate Military Affairs committees.

The latest measure still further jeopardizing medical education and medical care was the passage of the Army appropriation bill by Congress June 21. This bill includes the following provision:

Provided That no appropriation contained in this Act shall be available for any expense incident to education of persons in medicine (including veterinary) or dentistry if any expense on account of this education in such subjects was not being defrayed out of appropriations for the military establishment for the fiscal year 1944 prior to June 7, 1944. . . .

This provision would seem to eliminate from 1946 entering medical classes the 28 per cent of places contracted for by the Army. Even if the Navy increases its quota from 25 per cent to 31 per cent, schools will be obliged to obtain 69 per cent of their students from women and physically disqualified males. Nothing even approaching this number of qualified civilian students is available. Classes will probably be half filled in the country at large.

Should an adjustment not be made to correct the present alarming situation, a tremendous reduction of graduates after the war will ensue. Although schools will continue the accelerated program, they will admit classes only once annually instead of every nine months.

This of itself will reduce the number of graduates from the present annual average of 7,000 to 5,000. If classes can be only half filled, this number will be reduced to 2,500 graduates per year. Since 3,300 to 3,500 physicians die each year, there will result an annual and cumulative deficit of 2,000 doctors a year.

Still further reductions in graduates and permanent damage to the "plant" of medical education will result from some schools being forced to close their doors because of drastically curtailed enrolments. An unknown number of war casualties among medical officers will also reduce the supply of physicians.

These reductions in medical graduates will occur in the face of new and increased demands for medical services, mainly from the civilian population, the standing army and navy, the Veterans Administration and the liberated countries of Europe.

Full support should be forthcoming from the medical profession for the Miller bill (H. R. 5128), with modifications, which reads:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section 5 of the Selective Training and Service Act of 1940, as amended, is amended by inserting at the end thereof a new subsection reading as follows:

"(n) There shall be deferred from training and service under this Act in the land and naval forces of the United States, as necessary to the maintenance of the national health, safety, and interest, in each calendar year not less than six thousand medical students and not less than four thousand dental students. As used in this subsection the term 'medical or dental student' means (1) a person who is enrolled in, and who is pursuing a course of instruction prescribed for the degree of doctor of medicine at an accredited medical college; and a person who is enrolled in, and who is pursuing a course of instruction prescribed for the degree of doctor of dentistry at an accredited dental college; or (2) a person who is pursuing a regular course of instruction at an accredited college or university (satisfactory completion of which will make such person eligible for enrolment in an accredited medical or dental college) with the bona fide intention of entering an accredited medical or dental college and pursuing and completing the course of instruction prescribed for the degree of doctor of medicine or for the degree of doctor of dentistry."

Protests against the blind disregard for medical care in the future should be addressed to the Senate (Senator Robert R. Reynolds, Chairman) and House (Representative Andrew J. May, Chairman) Committees on Military Affairs, the Senate Committee on Education and Labor (Senator Elbert D. Thomas, Chairman) and the House Committee on Education (Representative Graham A. Barden, Chairman). Every state medical society, medical school and medical scientific society should express itself in no uncertain terms on these developments.

TONSILLECTOMY AND POLIOMYELITIS.

In the relationship between tonsillectomy and poliomyelitis two clinical facts seem to have been established, as emphasized in an editorial in *THE JOURNAL*:¹ (1) Acute poliomyelitis developed more often among recently tonsillectomized children, and (2) the increased incidence was due entirely to the excess of cases of the bulbar type. In his review of the available data Aycock² pointed out that the less common bulbar form predominated in the combined statistics over the spinal form in a ratio of about five to one in the cases occurring within thirty days following tonsillectomy. The operation of tonsillectomy and adenoidectomy, therefore, appears to bear in the thirty day group a causal relationship to acute poliomyelitis, especially the bulbar type of the disease.

A communication by Page³ in a recent issue of the *Archives of Otolaryngology* reports 1 case of poliomyelitis following 8,915 tonsillectomies. In his study, questionnaires were sent by the Manhattan Eye, Ear and Throat Hospital to 27,489 patients tonsillectomized during the years 1937 to 1941 inclusive. A total of 8,915 replies were received to the question "Have you had any illness since the tonsillectomy? What were the nature and the date of illnesses, if any?" The finding of only 1 case of acute poliomyelitis following 8,915 tonsillectomies assumes particular importance, since these were the years in which the disease was most prevalent. For 1941, when 404 cases of poliomyelitis with eight deaths were reported by the New York Department of Health, 7,500 cards were sent out and 3,500 replies were returned without illnesses reported. Stillerman and Fischer⁴ found in the epidemic of poliomyelitis in New York City that among 686 patients with poliomyelitis admitted to the Willard Parker Hospital in 1935 there were 10 in whom tonsillectomy and adenoidectomy had been performed during the month antedating their illness. In 8 of these patients symptoms of poliomyelitis were manifest within ten to twelve days after the operation. Six of the patients had the bulbar or encephalitic form of the illness. Inquiry by the same authors among 52 patients admitted to the same hospital in 1937 disclosed that 3 had been tonsillectomized within the month preceding the disease. Operation was performed on 2 of these fourteen days and on the third twenty-one days before the onset of the disease. All 3 had the bulbar type, and all of them died.

1. Tonsillectomy and Poliomyelitis, editorial, *J. A. M. A.* **118**: 980 (March 21) 1942.

2. Aycock, W. L.: Tonsillectomy and Poliomyelitis, *Medicine* **21**: 65 (Feb.) 1942.

3. Page, John Randolph: Tonsillectomy and Poliomyelitis: One Case of Poliomyelitis Following 8,915 Tonsillectomies, *Arch. Otolaryng.* **39**: 323 (April) 1944.

4. Stillerman, Maxwell, and Fischer, Alfred E.: Acute Bulbar Poliomyelitis Following Recent Tonsillectomy and Adenoidectomy, *Am. J. Dis. Child.* **56**: 778 (Oct.) 1938.

The discrepancy in the statistics of Page and those of Stillerman and Fischer and of Aycock and others is no doubt due to the method of investigation. The majority of the workers in this field would probably still support the warning sounded in the editorial of *THE JOURNAL*: Since tonsillectomy is almost always selective as to time, it would appear desirable that it be performed during the season which does not coincide with the prevalence of poliomyelitis.

Current Comment

ABNORMAL SECRETION OF THE PANCREAS AND OTHER GLANDS A SYSTEMIC DISEASE

According to Farber¹ and his associates obstructive conditions in the pancreas early in life are associated with meconium ileus in the neonatal period and later with nutritional disturbances, in which the celiac syndrome and serious respiratory disease predominate. Farber deals particularly with the pancreas, the respiratory system, the liver and the salivary glands of young children with pancreatic insufficiency. In the pancreas he found more or less complete atrophy of the exocrine parenchyma associated with and apparently due to the accumulation of inspissated secretion in the acini and in the variously dilated ducts. In what seemed to be the early stage of the process the acini and smaller ducts contained eosinophilic homogeneous masses that would cause obstruction to the outflow of pancreatic juice as suggested by Wolbach some years ago. In such cases the duodenal contents did not give evidence of the activity of pancreatic enzyme. In the patients with the symptoms and lesions of obstructive pancreatic achylia who lived more than a few months after birth, both the lungs nearly always showed effects of obstruction in the trachea, the bronchi and the bronchioles by thick, tenacious mucoid and mucopurulent material. The mucous glands of the trachea and bronchi were distended with material like that in the pancreatic acini and ducts. This was the case also in the salivary glands and the mucous glands of the esophagus, the duodenum, the gallbladder and the jejunum. The microscopic changes in the liver duplicated "in all important findings the lesions in the pancreas, even to the color and the appearance of the inspissated secretions." The pancreas may be only one of many glandular structures of which the secretions are subject to physical changes of as yet unknown nature that cause obstruction and dilatation of acini and ducts, with far reaching functional and anatomic consequences. "What has been called cystic fibrosis of the pancreas or pancreatic fibrosis is really a systemic disease with a variety of clinical appearances, the occurrence of which depends on when

the obstructive changes occur and which organs are affected." Better understanding of this disease calls for studies of the nature and causes of the alterations in the glandular secretions.

THE REPUBLICAN PLATFORM

Evidence of the extent to which the point of view of the medical profession is prevailing in the further development of medical service in the United States is apparent in those sections of the Republican platform adopted in Chicago last week which deal with this subject. Under the heading of Security the platform states:

Our goal is to prevent hardship and poverty in America. That goal is attainable by reason of the productive ability of free American labor, industry and agriculture, if supplemented by a system of social security on sound principles.

We pledge our support of the following:

1. Extension of the existing old age insurance and unemployment insurance systems to all employees not already covered.
2. The return of the public employment-office system to the states at the earliest possible time, financed as before Pearl Harbor.
3. A careful study of federal-state programs for maternal and child health, dependent children and assistance to the blind, with a view to strengthening these programs.
4. The continuation of these and other programs relating to health, and the stimulation by federal aid of state plans to make medical and hospital service available to those in need without disturbing doctor-patient relationship or socializing medicine.
5. The stimulation of state and local plans to provide decent low cost housing properly financed by the Federal Housing Administration, or otherwise, when such housing cannot be supplied or financed by private sources.

When the platform of the Democratic party becomes available, it also will be published in these columns.

CONTINUATION COURSES FOR PRACTICING PHYSICIANS

Elsewhere in this issue the Council on Medical Education and Hospitals lists the continuation courses available in all parts of the country to practicing physicians during the second half of 1944. These include courses in a wide variety of fields in clinical medicine and the basic sciences. The courses run for variable periods from one to several weeks. Some are concentrated full time courses and others are part time. This information is provided semiannually by the Council in response to a widespread demand which has persisted ever since the beginning of the war. A special effort at extensive coverage of available courses has been made in the current listing. Schools offering such courses will assist the Council by regularly providing information about them.

MEDICINE AND THE WAR

ARMY

ARMY PROVIDES MEDICAL KITS FOR PRISONERS HELD BY JAPANESE

The Army Medical Department has developed special medical supplies for shipment to the Far East in an effort to provide the best possible care for American prisoners under control of the Japanese. The specially packed supplies have been designed for distribution by the International Red Cross, and packing cases will be labeled in English and in Japanese. The new plan for making supplies available to American and Allied prisoners of the Japanese was developed by a committee of officers in the Office of the Surgeon General. Besides drugs, the shipments contain dressings, simple types of surgical and dental instruments, sterilizing equipment, insecticides and water purifiers. The shipments are prepared in three types of units: a 100 man unit containing five separate packages, a hospital unit and a bulk supplies unit. Ten 100 man units, plus the hospital and bulk supplies unit, contain supplies believed to be sufficient for the needs of 1,000 men for three months. In order to facilitate handling and make for easy recognition by non-English speaking labor the special plywood, waterproofed cases, each of which bears a large red cross and is addressed to the International Red Cross delegate, are painted in special colors according to the type of unit. The American Red Cross has requisitioned a number of units and has informed the Medical Department that it is hopeful that permission for distribution will be granted by the Japanese government.

Approximately 126 different drugs are provided, and each individual package of the 100 man unit contains a booklet with precise instructions, couched in simple, nontechnical terms, for use of the medicines. The 100 man unit contains those drugs which can be best used by laymen, while the hospital and bulk supplies units are intended for installations where professional services may be available. The medicines selected are those most useful in treating diseases known to be prevalent in the Far East and for ailments likely to beset persons living under prison camp conditions. Some of the diseases for which one or more medicines are prescribed, together with instructions for their use, are anemia, fevers, beriberi, blood poisoning, diarrhea, dysentery, skin infections, scurvy, pellagra, pneumonia, meningitis, ulcers and rickets.

As a result of the new supply plan, all shipments of British, Canadian and American medical supplies to prisoners of the Japanese in the future will be standardized and may be used interchangeably.

MOBILE X-RAY UNITS FOR INVASION

After several months of experimentation the European theater of operations chief surgeon's office has announced that mobile x-ray units will follow American troops onto the continent. Lieut. Col. Kenneth D. A. Allen of Denver, who conceived the idea in 1943 and followed it through successfully, stated that the primary purpose of the mobile units, as in all medical corps work, is to keep men in the fighting front by prompt, accurate diagnosis and by location of foreign bodies and to save lives. Hospitals in the field are unable to carry enough x-ray equipment to handle peak loads of patients, so mobile units will be rushed to them when needed. They may also be sent to clearing stations where no x-ray equipment is available. The personnel consists of one medical officer, a specialist in x-ray work and three enlisted men. Two blacked out tents attached to a tarpaulin covering the back of the truck serve as patients' waiting rooms and picture taking rooms. The back end of the truck is used for developing and drying x-ray films. Generators furnish power for drying film, for control of water temperature, for lighting and for powering the x-ray machine. Capt. Charles D. Rancourt of Albany, N. Y., who assisted Colonel Allen in the construction of the

unit, has been demonstrating the original unit before hundreds of medical corpsmen. Colonel Allen, senior consultant in radiology to the theater chief surgeon, has been in the Army since May 1942. He taught in the x-ray school at Fitzsimons General Hospital in Denver until he went to England in January 1943.

TYPHUS NO LONGER IMPERILS U. S. SOLDIERS

Brig. Gen. Leon A. Fox, field director of the U. S. Typhus Commission, recently stated that "typhus has been removed from the list of diseases fatal to the American soldier." General Fox was recently credited with having saved Naples last January from what might have been one of the worst typhus plagues in history and with having stopped the epidemic in record time. General Fox attributes this accomplishment to the Army's DDT powder and to the complete cooperation given to him by the commander of that area. In one day during the typhus epidemic in Naples General Fox's typhus team treated 73,000 people with DDT powder. Having arrived in Naples when the epidemic was just getting under way with the civilian population (December 20) General Fox went to work with his crew and by February 1, at a time when ordinarily there would be 500 cases a day reported, there were only 5 to 6 a day, and the epidemic was over. Although vaccinated against typhus, each soldier carries a small can of DDT powder.

WAC NEEDS ADDITIONAL TRAINED MEDICAL TECHNICIANS

The Women's Army Corps needs additional trained medical technicians. Physically qualified young women with high school education are urged to make application for enlistment in the WAC service with the medical department. Major Gen. Norman T. Kirk, Surgeon General of the Army, recently sent out an appeal for women volunteers in hospital work. The Army offers training to competent young women enlisted in the Women's Army Corps in the field of medical laboratory, dental, x-ray and other technical subjects.

STATE HOSPITAL LEASED TO ARMY

The new Edgewood State Hospital at Deer Park, L. I., has been turned over to the War Department to be used for hospital purposes. Under the terms the War Department will reimburse the state for actual expenses incurred at the institution, pay for depreciation on buildings and equipment and restore the hospital to its present state at the end of Army occupancy. The hospital is nearing completion and will accommodate 2,300 beds.

FLIGHT SURGEONS' ASSISTANTS

A class of forty-eight flight surgeons' assistants completed the six weeks course in aviation medicine at the School of Aviation Medicine, Randolph Field, Texas, June 9. These men are trained as specialists in assisting flight surgeons in the selection, care and maintenance of the flier. Brig. Gen. Eugen G. Reinartz, U. S. Army, is commandant of the school.

PROMOTIONS IN THE ARMY MEDICAL DEPARTMENT

The following promotions to the rank of brigadier general (temporary) were recently announced by the War Department:

Col. George B. Foster Jr., Salem, Mass.
Col. Henry C. Doeling, Clayton, N. J.
Col. Ralph G. DeVoe, Seattle.

ARMY AWARDS AND COMMENDATIONS

Major Daniel H. Maunz

The Soldier's Medal was recently awarded to Major Daniel H. Maunz, formerly of Bradford, Pa. The citation accompanying the award read "On receipt of information at an army air forces installation at Presque Isle, Maine, that a civilian cook with a detachment was seriously ill with acute appendicitis at River Clyde, Northwest Territory, Canada, and that no doctor was available, he tendered his services in a professional capacity. Since it was impossible to land a plane safely in the vicinity of River Clyde, he volunteered to make a parachute jump, although he had no previous experience, in order to reach his patient. On Nov. 18, 1943 the rescue plane reached River Clyde. He exited at 1,200 feet, landed successfully and performed an operation which undoubtedly saved the patient's life." Dr. Maunz graduated from the University of Buffalo School of Medicine in 1931 and entered the service Oct. 5, 1942.

Colonel Robert K. Simpson

The War Department recently announced the award of the Legion of Merit to Col. Robert K. Simpson, who "performed outstanding services from April 1941 to September 1943. As surgeon of the AAF Gulf Coast Training Center and later of the AAF Central Flying Training Command, he procured more than 300 eminent physicians and surgeons for commission in the Army. He revised hospital plans in keeping with climatic conditions, designed infirmaries and established an itinerant dental and veterinary service for civil contract schools. He organized and established schools for medical and postgraduate specialized training. He established air ambulance service for Matagorda Island and Peninsula, and recreation and convalescence areas. At the same time he provided medical service for indigent dependents of military personnel and a well functioning consultation service for smaller outlying stations. He devised an efficient hand phorometer that can be packed in the flight surgeon's physical examining set. All of his efforts contributed materially to the efficiency and orderly expansion of the Air Forces." Dr. Simpson graduated from the University of Texas Medical Branch, Galveston, in 1916.

MISCELLANEOUS

ABOLITION ON CIVILIAN DEFENSE
REGIONAL OFFICES

Administrative Order No. 38, recently published by the Office of Civilian Defense, Washington, D. C., abolishes all civilian defense regions excepting the Washington region, as provided for in Administrative Order No. 33, dated Feb. 25, 1943, as subsequently revised and amended, and all powers and duties that have been delegated by the director of civilian defense to the regional directors are rescinded. Regional offices of civilian defense and regional civilian defense boards are hereby disestablished. Supplies, equipment, records and personnel problems arising from such disestablishment shall be met on the basis of specific instructions to each regional director. The functions and services heretofore performed by regional offices under their delegated powers and duties shall be performed hereafter by the Washington office or by such other methods as the director shall determine. The order is effective as of July 1, 1944.

PUBLIC HEALTH UNDER HITLER

Nya Dagligt Allehanda for March 11, 1944 (Germany) STB reports: Certain German universities have introduced a numerus clausus for medical students owing to the unusually large number of enrolments. One newspaper interviewed the head of the medical school at Heidelberg and asked him whether medicine is now a fashionable subject. The dean demurred and said that the matter will gradually be regulated but that there is still a shortage of doctors. The German authorities, however, distrust the sudden enthusiasm for medicine among women students and decided to investigate the matter at Heidelberg. Every woman student was forced to produce papers proving that she did not suddenly decide to become a doctor but planned it during her attendance at school. Out of 200 students 170 were able to produce evidence and others were able to plead "extenuating circumstances." Investigations were easier with regard to the male students since the majority were in uniform and belonged to a student company sent home for studies. But only those who had previously enrolled with the faculty of medicine may be sent to the university from the front. Konjunkturmässige, a new German expression, therefore, have little chance of being included in these companies. Those who do not attend to their studies properly are immediately taken over by the labor organizations.

MEDICAL AND SURGICAL RELIEF
COMMITTEE OF AMERICA

A donation of 100,000 atabrine tablets, valued at \$1,500, was recently made by the Medical and Surgical Relief Committee of America (420 Lexington Avenue, New York 17) to the Friends Ambulance Unit in Calcutta to alleviate the suffering of malaria stricken victims among the civilian and military population in India. The committee also sent to India during the last month, in conjunction with the American Friends Service Committee, \$5,100 worth of drugs—sulfapyridine, sulfaguanidine and atabrine tablets.

COLE LABORATORIES AWARDED
ARMY-NAVY E PENNANT

The Cole Laboratories, Long Island City, N. Y. (of which Retort Pharmaceutical Company is a division) have received the Army-Navy E Award. The Cole Laboratories operate three plants, where continuous laboratory control is maintained to insure products being manufactured according to specifications.

AWARDED ARMY-NAVY E

The Wilnot Castle Company, manufacturers of sterilizing equipment, has been awarded the Army-Navy E for achievement in war production. The presentation was made Thursday, June 22. The ceremonies were held in Cutler Union on the University of Rochester Campus.

The March 13, 1944 issue of *Le Journal* (France) states that the number of cases of scabies treated in Saint-Louis Hospital in Paris alone varied from 8,005 in 1939 to 93,559 in 1943. Sometimes over 600 patients are treated daily. The old unpleasant method of treatment with soft soap baths plus helmerich ointment has now been given up for the new "120" treatment, namely the painting of the whole body twice within fifteen minutes with liquid derivative of benzoate of benzoyl.

The Vichy Home Service for March 3, 1944 (France) reports that in 1943 the doctors made a great effort to relieve those colleagues who since the Armistice have been providing the health service in the prisoners' camps; 470 serving military doctors have replaced 84 serving doctors and 382 reserve doctors in the stalags and oflags. Another 112 doctors have joined them; 29 of them are volunteers and 83 were sent by the State Secretariat for Health.

A German from the town of West Sternberg has been sentenced to death by a special court at Frankfurt for performing nine abortions, the Nazi DNB agency reported recently in a wireless dispatch to the German domestic press. The dispatch, reported by United States government monitors, said that the German had been sentenced under a new provision in the Nazi penal code.

ORGANIZATION SECTION

PROCEEDINGS OF THE CHICAGO SESSION

MINUTES OF THE NINETY-FOURTH ANNUAL SESSION OF THE AMERICAN
MEDICAL ASSOCIATION, HELD IN CHICAGO, JUNE 12-16, 1944

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:05 by Dr. Roy W. Scott, Cleveland, in the absence of Dr. Burrell O. Raulston, Los Angeles, the chairman of the section.

Lieut. Col. Thomas H. Sternberg and Col. Thomas B. Turner, M. C., A. U. S., presented a paper on "The Treatment of Sulfonamide Resistant Gonorrhea with Penicillin Sodium." Discussed by Lieut. Col. Irving S. Wright, M. C., A. U. S.; Dr. John F. Maloney, U. S. P. H. S.; Lieut. Col. Thomas H. Sternberg, M. C., A. U. S.; Dr. Alfred Cohn, New York, and Col. Thomas B. Turner, M. C., A. U. S.

Dr. Frank N. Allau, Boston, read a paper on "The Clinical Management of Weakness and Fatigue." Discussed by Drs. Walter C. Alvarez, Rochester, Minn.; Benjamin F. Sieve, Boston; Walter Freeman, Washington, D. C., and Frank N. Allan, Boston.

Dr. Louis Hamman, Baltimore, read the Frank Billings Lecture, on "Mediastinal Emphysema."

Drs. Hobart A. Reimann, Alison H. Price and John H. Hodges, Philadelphia, presented a paper on "Epidemic Diarrhea, Nausea and Vomiting of Unknown Cause." Discussed by Drs. H. J. Shaughnessy, Chicago; Ruth E. Tayler, Chicago; J. A. Garcia, Corpus Christi, Texas; D. J. Sandweis, Detroit, and Hobart A. Reimann, Philadelphia.

Dr. Howard F. Root, Boston, read a paper on "Treatment of Diabetic Coma." Discussed by Drs. Edward S. Dillon, Philadelphia; Rollin T. Woodyatt, Chicago; Samuel Soskin, Chicago; Fred M. Allen, New York, and Howard F. Root, Boston.

THURSDAY, JUNE 15—MORNING

The following officers were elected: chairman, Dr. W. D. Stroud, Philadelphia; vice chairman, Dr. W. O. Thompson, Chicago; secretary, Dr. Cecil J. Watson, Minneapolis; delegate, Dr. F. M. Smith, Iowa City; alternate, Dr. Charles T. Stone, Galveston, Texas; executive committee: Dr. Roy W. Scott, Cleveland; Dr. Burrell O. Raulston, Los Angeles, and Dr. W. D. Stroud, Philadelphia; member of the American Board of Internal Medicine, Dr. B. O. Raulston, Los Angeles.

Col. Leonard G. Rowntree, M. C., A. U. S., read a paper on "The Health Needs of the Nation as Reflected by the Examination of Thirteen Million Registrants." Discussed by Dr. Raymond W. Waggoner, Ann Arbor, Mich.; Gen. George Lull, M. C., A. U. S., and Drs. R. L. Sensenich, South Bend, Ind.; Walter Freeman, Washington, D. C., and Herbert F. Robb, Belleville, Mich.

Dr. Robert L. Levy, New York, Brig. Gen. Charles C. Hillman, U. S. Army, and Drs. William D. Stroud, Philadelphia, and Paul D. White, Boston, presented a paper on "Transient Hypertension: Observations Based on Analysis of the Medical Records of 22,741 Officers of the United States Army."

Dr. Reginald H. Smithwick, Boston, read a paper on "The Results of Radical Sympathectomy in Hypertension."

Dr. Walter Kempner, Durham, N. C., read a paper on "Treatment of Kidney Disease and Hypertensive Vascular Disease with Rice Diet."

These three papers were discussed by Drs. E. A. Hines Jr., Rochester, Minn.; Geza de Takats, Chicago; Roy W. Scott, Cleveland; I. H. Page, Indianapolis; Frederick M. Hanes, Durham, N. C.; N. S. Davis III, Chicago; William S. Collens, Brooklyn; Walter Kempner, Durham, N. C.; Robert L. Levy, New York, and Reginald H. Smithwick, Boston.

Lieut. Col. Harry M. Kirschbaum, M. C., A. U. S., read a paper on "Heart Sounds: Recording of Effects of Anoxia."

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Experimental Medicine and Therapeutics.

Col. W. Paul Holbrook, M. C., A. U. S., read a paper on "Acute Rheumatic Fever in the Army Air Forces."

Comdr. Alvin F. Coburn (MC), U.S.N.R., read a paper on "The Application of Sulfadiazine Prophylaxis in the Prevention of Bacterial Infections of the Respiratory Tract."

These two papers were discussed by Dr. T. Duckett Jones, Boston; Capt. Richard G. Hodges, M. C., A. U. S.; Col. W. Paul Holbrook, M. C., A. U. S., and Comdr. Alvin F. Coburn (MC), U.S.N.R.

Col. Julien E. Benjamin, M. C., A. U. S., and Major Ralph C. Hoyt, M. C., A. U. S., presented a paper on "Postvaccinal (Yellow Fever) Hepatitis: Convalescent Stage."

Dr. John R. Paul, New Haven, Conn., and Capt. W. P. Havens Jr., M. C., A. U. S., presented a paper on "Infectious Hepatitis in the Mediterranean Area."

These two papers were discussed by Dr. Joseph Stokes Jr., Philadelphia; Major Joseph Bank, El Paso, Texas; Col. Julien E. Benjamin, M. C., A. U. S., and Dr. John R. Paul, New Haven, Conn.

The following papers were read in a symposium on "Vitamins, Amino Acids and Enzymes," followed by a panel discussion, of which Morris Fishbein, Chicago, was Moderator:

Dr. William M. Govier, Winston-Salem, N. C.: "The Rationale for the Use of Vitamins in the Therapy of Shock and Anoxia."

Dr. Elmer L. Sevringhaus, Madison, Wis.: "Adult Needs of Vitamins A and C."

Dr. A. J. Carlson, Chicago: "The Dilemma of Subclinical Vitamin Deficiencies."

Dr. Tom D. Spies, Birmingham, Ala.: "Vitamins in the Practice of Medicine."

SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Frederick A. Collier, Ann Arbor, Mich.

Dr. George D. Lilly, Miami, Fla., read a paper on "Alcoholic Injection of the Lumbar Sympathetic Trunk in Cases of Peripheral Vascular Insufficiency When Surgical Sympathectomy Is Contraindicated." Discussed by Dr. Arthur W. Allen, Boston.

Dr. Keith S. Grimson, Durham, N. C., read a paper on "The Effect of Activity, Rest, Natural Sleep, Sodium Amytal, Pentothal Sodium, Chloralose and Ether on Experimental Neurogenic

Hypertension." Discussed by Drs. Geza de Takats, Chicago, and Emmet B. Bay, Chicago.

Dr. I. A. Bigger, Richmond, Va., read a paper on "The Management of Traumatic Aneurysms and Arteriovenous Fistulas." Discussed by Drs. John DeJ. Pemberton, Rochester, Minn., and Waller Overton Bullock, Lexington, Ky.

Dr. Geza de Takats, Chicago, read a paper on "The Causal State in Peace and War." Discussed by Dr. Warren H. Cole, Chicago.

Dr. Arthur W. Allen, Boston, read a paper on "Femoral Vein Interruption for the Treatment of Phlebothrombosis and Pulmonary Embolism." Discussed by Dr. Alton Ochsner, New Orleans.

Drs. John H. Garlock and Burrill B. Crohn, New York, presented a paper on "An Appraisal of the Results of Surgery in the Treatment of Regional Ileitis." Discussed by Drs. Henry W. Cave, New York; Claude F. Dixon, Rochester, Minn., and Burrill B. Crohn, New York.

Dr. Rawley M. Penick Jr., New Orleans, read a paper on "Problems in the Surgical Treatment of Congenital Megacolon." Discussed by Drs. J. Arnold Bagen, Rochester, Minn.; Reginald H. Smithwick, Boston; K. S. Grimson, Durham, N. C., and Arthur W. Allen, Boston.

THURSDAY, JUNE 15—AFTERNOON

The following officers were elected: chairman, Lieut. Col. Daniel C. Elkin, M. C., A. U. S.; vice chairman, Dr. William A. Andrews, Johnson City, N. Y.; secretary, Dr. Alton Ochsner, New Orleans; delegate, Col. Grover Penberthy, M. C., A. U. S.; alternate, Dr. I. A. Bigger, Richmond, Va.; member of board of governors, American College of Surgeons, Dr. Walter G. Phippen, Salem, Mass., and Dr. Charles S. Kennedy, Detroit; representatives on Committee on Industrial Health of the Section on Surgery: chairman, Dr. S. Perry Rogers, Chicago; Dr. William L. Estes, Bethlehem, Pa.; Dr. Henry C. Marble, Boston, and Dr. Thomas M. Joyce, Portland, Ore., and Dr. John Huber Wagner, Pittsburgh; representative to Scientific Exhibit, Dr. Owen H. Wagensteen, Minneapolis; executive committee: Dr. Arthur W. Allen, Boston; Dr. Frederick A. Collier, Ann Arbor, Mich., and Lieut. Col. Daniel C. Elkin, M. C., A. U. S.

Dr. Carl Bearse, Boston, read a paper on "Gallstones: The Time Factor in the Development of Complications." Discussed by Drs. I. S. Otis, Meriden, Conn.; John M. Fallon, Worcester, Mass., and Otto De Muth, Vancouver, B. C.

Dr. Frederick A. Collier, Ann Arbor, Mich., read the chairman's address, entitled "Blood Loss During Operation."

Drs. Warren H. Cole, Danely P. Slaughter and Lewis J. Rossiter, Chicago, presented a paper on "Potential Dangers of Nontoxic Nodular Goiter." Discussed by Drs. Frank H. Lahey, Boston; George M. Curtis, Columbus, Ohio; Brien T. King, Seattle, and Danely P. Slaughter, Chicago.

Dr. Forrest O. J. Young, Rochester, N. Y., read a paper on "The 'Suture' of Wounds by Plasma-Thrombin Adhesion." Discussed by Drs. R. T. Tidrick, Iowa City; E. D. Warner, Iowa City, and W. J. Carson, Milwaukee.

Drs. Frank E. Adair and Norman Treves, New York, Lieut. Comdr. Joseph H. Farrow (MC), U.S.N.R., and Isabelle M. Scharnagel, New York, presented a paper entitled "A Report of the Clinical Effects of Surgical and X-Ray Castration in Mammary Cancer." Discussed by Drs. Lawrence A. Pomeroy, Cleveland; J. Shelton Horsley, Richmond, Va.; W. E. Chamberlain, Philadelphia, and Norman Treves, New York.

Drs. Willard H. Parsons and John C. Henthorne, Vicksburg, Miss., and Major R. Lee Clark Jr., M. C., A. U. S., presented a paper on "Plasma Cell Mastitis." Discussed by Drs. Warren H. Cole, Chicago; R. L. Sanders, Memphis, Tenn.; Frank E. Adair, New York, and John C. Henthorne, Vicksburg, Miss.

FRIDAY, JUNE 16—AFTERNOON

A joint meeting was held with the Section on Gastro-Enterology and Proctology. The proceedings are reported in the minutes of that section.

SECTION ON OBSTETRICS AND GYNECOLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Louis E. Phaneuf, Boston.

Dr. Richard Torpin, Augusta, Ga., read a paper on "The Influence of the Placental Site on Fetal Presentation."

Drs. Louis R. Limarzi and John R. Wolff, Chicago, presented a paper on "The Anemias of Pregnancy: A Clinical and Hematologic Study Based on the Correlation of the Peripheral Blood and Bone Marrow Findings." Discussed by Drs. William J. Dieckmann, Chicago; Howard L. Alt, Evanston, Ill.; Frank H. Bethell, Ann Arbor, Mich., and Louis R. Limarzi, Chicago.

Drs. William F. Mengert, Dallas, Texas, and Lieut. (jg) Lester D. Odell (MC), U.S.N.R., presented a paper on "The Overweight Obstetric Patient." Discussed by Drs. Fred H. Falls, Chicago; Newlin F. Paxson, Philadelphia, and William F. Mengert, Dallas, Texas.

Dr. Priscilla White, Boston, read a paper on "Diabetes in Pregnancy." Discussed by Drs. Henry Dolger, New York; William J. Dieckmann, Chicago; R. Carrasco-Formiguera, Puebla, Mexico, and Priscilla White, Boston.

Drs. Rupert E. Arnell, New Orleans, and Daniel W. Goldman, Shreveport, La., presented a paper on "Protein Deficiencies in Pregnancy." Discussed by Drs. Philip F. Williams, Philadelphia; Wilfred N. Sisk, Asheville, N. C., and Rupert E. Arnell, New Orleans.

Dr. Curtis J. Lund, Minneapolis, read a paper on "Nutrition in Pregnancy." Discussed by Dr. Fred L. Adair, Chicago.

The chairman appointed Drs. George W. Kosmak, New York, and Marvin Pierce Rucker, Richmond, Va., to fill vacancies on the executive committee.

THURSDAY, JUNE 15—MORNING

The following officers were elected: chairman, Dr. Philip F. Williams, Philadelphia; vice chairman, Dr. Francis Bayard Carter, Durham, N. C.; secretary, Dr. William F. Mengert, Dallas, Texas; executive committee: Dr. Walter T. Dammreuther, New York; Dr. Louis E. Phaneuf, Boston; Dr. Philip F. Williams, Philadelphia; members of board of governors, American College of Surgeons: Dr. Emil Novak, Baltimore; Dr. Thomas K. Brown, St. Louis, and Dr. Alice Maxwell, San Francisco; representatives to American Committee of Maternal Welfare: Dr. R. D. Mussey, Rochester, Minn.; Dr. W. B. Thompson, Los Angeles, and Dr. Oren Moore, Charlotte, N. C.; representatives on American Board of Obstetrics and Gynecology: Dr. Francis Baird Carter, Durham, N. C.; Dr. Louis E. Phaneuf, Boston, and Dr. Ludwig A. Emge, San Francisco.

A report of the Committee on the Health of Women in Industry was presented by Dr. H. Close Hesselstine, Chicago, chairman.

Drs. Catharine Macfarlane and Margaret C. Sturgis, Philadelphia, presented a paper on "The Value of Periodic Pelvic Examination in the Control of Cancer of the Uterus." Discussed by Drs. Norman Treves, New York, and Augusta Webster, Chicago.

Drs. Lewis C. Scheffey and David M. Farrell, Philadelphia, presented a paper on "The Role of Injudicious Hormonal Therapy in the Delayed Diagnosis of Uterine Cancer." Discussed by Drs. Edward D. Allen, Chicago; Joe Vincent Meigs, Boston; James A. Corcadan, New York; Karl H. Marteloff, Portland, Ore.; Richard W. TeLinde, Baltimore, and Karl J. Karnack, Houston, Texas.

Dr. Clyde L. Randall, Buffalo, read a paper on "Recognition of Women Predisposed to Adenocarcinoma of the Uterus." Discussed by Drs. Herbert E. Schmitz, Chicago, and Louis C. Kress, Albany, N. Y.

Dr. James A. Corcadan, New York, read a paper on "Evaluation of Radiation in the Treatment of Carcinoma of the Cervix." Discussed by Drs. Lewis C. Scheffey, Philadelphia; H. F. Schmitz, Chicago, and Clyde L. Randall, Buffalo.

Dr. Richard W. Telinde, Baltimore, read a paper on "The Treatment of Uterine Prolapse and Associated Conditions." Discussed by Drs. George H. Gardner, Chicago; Roland S. Cron, Milwaukee; J. E. Cannaday, Charleston, W. Va.; John M. Fallon, Worcester, Mass.; Channing W. Barrett, Chicago; R. C. Austin, Dayton, Ohio; C. Gordon Johnson, New Orleans, and K. M. Martzloff, Portland, Ore.

Dr. Louis E. Phancuf, Boston, read a paper on "The Progress of Gynecology During the Last Quarter of a Century."

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Urology.

Dr. E. Granville Crabtree, Boston, read a paper on "Use of the Sulfonamide Drugs in Pylonephritis in Pregnancy." Discussed by Drs. Jacob F. Greenhill, Chicago; Goodrich C. Schaffner, Portland, Ore.; Budd C. Corbus, Chicago, and A. J. Kobak, Chicago.

Dr. J. M. Hundley Jr., Baltimore, read a paper on "Influence of Gynecologic Disorders on Urinary System" Discussed by Drs. Nelse F. Ockerblad, Kansas City, Mo., and Vincent J. O'Connor, Chicago.

Dr. George H. Gardner, Chicago, read a paper on "Infertility: Our Responsibilities in Diagnosis." Discussed by Drs. Robert M. Grier, Evanston, Ill.; Ralph A. Reis, Chicago; V. D. Lespinasse, Chicago; Henry K. Sangree, Philadelphia; A. R. Abarbanel, Washington, D. C.; C. J. Stamm, Philadelphia, and Jacob P. Greenhill, Chicago.

Drs. Herman L. Kretschmer and Noble Sproat Heaney, Chicago, presented a paper on "Pylitis of Pregnancy: Foci of Infection in Prophylaxis."

Dr. A. I. Folsom, Dallas, read a paper on "The Female Urethra."

These two papers were discussed by Drs. Vincent J. O'Connor, Chicago; V. D. Lespinasse, Chicago; H. W. Howard, Portland, Ore., and Lieut. Col. Harry M. Kerschbaum, M. C., A. U. S.

Lieut. Col. L. W. Riba, M. C., A. U. S., read a paper on "Sulfonamide Resistant Gonorrhea Treated with Penicillin: Report of 450 Cases."

SECTION ON OPHTHALMOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Conrad Berens, New York.

Dr. Conrad Berens, New York, read the chairman's address, entitled "The Making of an Ophthalmologist"

Dr. William L. Benedict, Rochester, Minn., the Guest of Honor, read a paper entitled "Diagnosis of Orbital Tumors."

Drs. Hayes Martin and Algernon B. Reese, New York, presented a "Progress Report on the Treatment of Bilateral Retinoblastoma by Surgery and Irradiation with the Purpose of Conserving Vision in One Eye." Discussed by Drs. A. F. M. de Roeth, Spokane, Wash.; Richard C. Gamble, Chicago, and Algernon B. Reese, New York.

Dr. C. L. Pannabecker, Ann Arbor, Mich., read a paper on "Neuroparalytic Keratitis: Ocular Complications Following Operations for Trigeminal Neuralgia." Discussed by Drs. A. D. Ruedemann, Cleveland; Major J. M. Masters, M. C., A. U. S., and C. L. Pannabecker, Ann Arbor, Mich.

Drs. Herman M. Burian and Kenneth N. Ogle, Hanover, N. H., presented a paper on "Meridional Aniseikonia at Oblique Axes." Discussed by Drs. Lawrence T. Post, St. Louis; Ernest A. W. Sheppard, Washington, D. C., and Hermann M. Burian, Hanover, N. H.

THURSDAY, JUNE 15—AFTERNOON

Executive Session

It was voted that the minutes of the last executive meeting be approved as printed in the transactions.

The Howe Research Medal was awarded posthumously to Dr. Sanford R. Gifford.

Dr. R. J. Masters, secretary, reported that there was no report from the Committee on Visual Economics.

Dr. Lawrence T. Post, St. Louis, read the report of the American Committee on Optics and Visual Physiology, which was accepted.

Dr. Masters reported that the Committee on the Awarding of the Knapp Medal recommended that the Knapp Medal be not awarded this year. The report was accepted.

The following committee for awarding the Knapp Medal for 1945 was elected from the floor: Dr., A. Ray Irvine, Los Angeles; Dr. F. A. Davis, Madison, Wis., and Frederick Herman Verhoeff, Boston.

Dr. S. Judd Beach, Portland, Maine, read the report of the American Board of Ophthalmology, which was accepted.

Dr. J. S. Friedenwald, Baltimore, presented a report for the Committee on National Museum of Ophthalmic Pathology. The report was accepted.

Dr. Masters presented the report of the Committee on Scientific Exhibit, which was accepted, and a vote of thanks extended Dr. Georgiana D. Theobald.

Dr. Robert von der Heydt, Chicago, reported that there had been no objects of interest contributed to the Museum of Ophthalmic History during the past two years.

Dr. Walter B. Lancaster, Hanover, N. H., read the report of the Committee on Orthoptics, which was accepted.

Dr. William L. Benedict, Rochester, Minn., reported that the Committee of the Student Health Association of the National Educational Association had been inactive during the past eighteen months, owing to several members entering military service.

Dr. Arthur J. Bedell, Albany, N. Y., reported as delegate of the section to the House of Delegates, and the report was accepted with thanks.

Dr. Parker Heath, Detroit, reported that the Committee on Ophthalmic Literature had been relatively inactive and recommended that the committee be continued. The report was accepted.

Dr. Albert C. Snell, Rochester, N. Y., read the report of the Committee on Industrial Ophthalmology. The report was accepted.

Dr. William L. Benedict, Rochester, Minn., in reporting as representative of the Council on Pan American Council, said that the Congress scheduled to be held in Montevideo in 1944 was canceled but that plans were proceeding for a congress in Montevideo in November 1945.

Dr. Parker Heath, Detroit, presented the report of the Knapp Testimonial Fund Committee. The report was accepted.

Dr. Lawrence T. Post, St. Louis, reported for Dr. Hayward Post, representative of the section to the Board of Governors of the College of Surgeons, that there had been no College of Surgeons meeting since his appointment.

Dr. Albert C. Snell, Rochester, N. Y., read the report of the executive committee as follows: The executive committee, in accord with a ruling by the Secretary of the American Medical Association, has continued to function in the interval between the last meeting of this section in June 1942 and this meeting. The following are the important acts of this committee: 1. The election of a permanent secretary. 2. The presentation of a number of papers as two symposiums on ophthalmologic subjects, which were published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, since no transactions of the Section on Ophthalmology were published in 1943. The symposiums covered two general topics as follows: A. Ocular therapeutics: 1. Fever therapy. F. C. Cordes. 2. Chemotherapy. Parker Heath. 3. Epidemic keratoconjunctivitis (The Epidemiology of). A. J. Bedell. B. Ophthalmology in the War Years: 1. Ocular Complications of Head Injuries. D. J. Lyle. 2. Eye Problems Resulting from the Stepped Up War Program in Industry. Hedwig Kuhn. 3. Eye Injuries. C. P. Clark. 4. Intraocular Foreign Bodies. Edward Stieren. 3. Appointment of vacancies in various committees. 4. The arrangement of the program for the present meeting, for the success of which we are largely indebted to our efficient secretary, Dr. Robert Masters. The report was accepted.

The executive committee recommended that A. The following committees be continued unchanged: (a) Committee on Visual Economics. (b) Committee on National Museum of Ophthalmic

Pathology (Joint). (c) Committee on Scientific Exhibits from Section. (d) Committee on Museum of Ophthalmic History. (e) Committee on Ophthalmic Literature. (f) Committee on Industrial Ophthalmology. (g) Knapp Testimonial Fund Committee. (h) Representative to Council, Pan American Congress. (i) Representative of Section to Board of Governors, College of Surgeons. B. That the following committees be continued with appointments for each respective committee: (a) American Committee on Optics and Visual Physiology. Dr. Walter B. Lancaster to replace Dr. Gifford. Dr. Thomas Allen to be appointed. (b) Orthoptic Council. Dr. Truman Boyer to replace Maynard Wheeler. (c) American Board of Ophthalmology. Dr. Everett L. Goar, for four years, to replace Dr. S. Judd Beach. The report was accepted.

The executive committee recommended that the Council on Industrial Health be authorized to continue the work of the special committee on research and reports and that this committee be given sufficient financial support for the employment of adequate personnel in the headquarters office to promote the activities of this committee. The recommendation was accepted.

The executive committee recommended that the section appoint a committee of five on optical dispensing, this committee to undertake a thorough study of all phases of the dispensing of optical services and supplies, and that the American Medical Association be requested to appropriate a sum of \$2,500 or as much thereof as may be necessary, that this committee may be able to employ adequate personnel to carry out the purposes of this committee. The recommendation was accepted.

The executive committee recommended that the project of testing and standardizing tonometers, sponsored by the Academy of Ophthalmology and Otolaryngology, be approved and endorsed by the section. The recommendation was accepted.

The executive committee recommended that a committee of five on ophthalmic public relations be appointed. The recommendation was accepted.

The executive committee reported that a tentative resolution had been prepared by the executive committee concerning the relations of ophthalmology with optometry, which it would refer to the newly appointed Committee on Ophthalmic Public Relations.

The following officers were elected: chairman, Dr. Frederick C. Cordes, San Francisco; vice chairman, Dr. Grady E. Clay, Atlanta, Ga.; secretary, Dr. Robert J. Masters, Indianapolis; delegate, Dr. Arthur J. Bedell, Albany, N. Y.; alternate, Dr. A. D. Ruedemann, Cleveland.

Scientific Session

Dr. Peter C. Kronfeld, Chicago, read a paper entitled "In Search of Gonioscopic Correlates of Responsiveness to Miotics in Glaucoma." Discussed by Drs. H. Isabelle McGarry, Chicago; John M. McLean, New York; C. W. Ascher, Cincinnati, and Peter C. Kronfeld, Chicago.

Dr. Paul A. Chandler, Boston, read a paper on "Choice of Operation in Glaucoma." Discussed by Drs. Edward C. Ellett, Memphis, Tenn.; Harry S. Gradle, Chicago; John M. McLean, New York, and Paul A. Chandler, Boston.

Dr. Kenneth C. Swan, Iowa City, read a paper on "Dibutoline: A New Mydriatic and Cycloplegic Drug." Discussed by Drs. S. Judd Beach, Portland, Maine; Jonas S. Friedenwald, Baltimore; William H. Crisp, Denver, and Kenneth C. Swan, Iowa City.

Dr. Ralph O. Rychener, Memphis, Tenn., read a paper on "The Management of Traumatic Hyphemia." Discussed by Drs. F. Bruce Fralick, Ann Arbor, Mich.; Hugo L. Bair, Rochester, Minn.; William B. Clark, New Orleans; Paul A. Chandler, Boston, and Ralph O. Rychener, Memphis, Tenn.

Dr. Harvey E. Thorpe, Pittsburgh, read a paper on "Non-magnetic Intraocular Foreign Bodies." Discussed by Drs. Edmund B. Spaeth, Philadelphia; Major Meyer H. Riwchun, M. C., A. U. S., and Harvey E. Thorpe, Pittsburgh.

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Laryngology, Otolaryngology and Rhinology.

The following papers were read as a symposium on "The Treatment of Chronic Dacryocystitis":

Dr. Harold Gifford Jr., Omaha: "Discussion of Dacryocystitis from the Point of View of the Ophthalmologist."

Dr. Laverne B. Spake, Kansas City, Kan.: "Treatment of Chronic Dacryocystitis from the Point of View of the Rhinologist."

These two papers were discussed by Drs. Charles T. Porter, Boston; Joseph I. Kemler, Baltimore; H. P. Mosher, Boston; Lawrence B. Spake, Kansas City, Kan., and Harold Gifford Jr., Omaha.

The following papers were read as a symposium on "The Use of Penicillin in the Treatment of Diseases of the Eye, Ear, Nose and Throat":

Lieut. Col. John E. L. Keyes, M. C., A. U. S.: "Use of Penicillin in Diseases of the Eye."

Capt. C. A. Swanson (MC), U.S.N., and Lieut. D. C. Baker (MC), U.S.N.R.: "The Use of Penicillin in Diseases of the Ear."

Capt. F. J. Putney, M. C., A. U. S.: "The Use of Penicillin in Diseases of Nose and Throat."

These three papers were discussed by Major Elmer A. Vorisek, M. C., A. U. S.; Major Walter J. Aagesen, M. C., A. U. S.; Comdr. E. E. Koebbe, U.S.N.R., U. S. Naval Hospital, Great Lakes, Ill.; Capt. Robert Henner, Barksdale Field, Louisiana; Capt. F. J. Putney, M. C., A. U. S.; Capt. C. A. Swanson (MC), U.S.N., and Lieut. Col. John E. L. Keyes, M. C., A. U. S.

SECTION ON LARYNGOLOGY, OTOLARYNGOLOGY AND RHINOLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Claude C. Cody, Houston, Texas.

Drs. Fred Z. Havens and William C. Thornell, Rochester, Minn., presented a paper on "Malignant Tumors of the Nasal Cavity." Discussed by Drs. Thomas E. Carmody, Denver; Thomas C. Galloway, Evanston, Ill., and Fred Z. Havens, Rochester, Minn.

Dr. Barney M. Kully, Los Angeles, read a paper on "The Use and Abuse of Nasal Vasoconstrictors." Discussed by Drs. Lawrence R. Boies, Minneapolis; O. E. Van Alyea, Chicago, and Barney M. Kully, Los Angeles.

Dr. Harry L. Baum, Denver, read a paper on "Treatment of Acute Laryngotracheobronchitis." Discussed by Drs. T. Roy Gittins, Sioux City, Iowa; Paul H. Holinger, Chicago; Otto Jason Dixon, Kansas City, Mo.; Fred Z. Havens, Rochester, Minn.; Lieut. Comdr. J. J. Potter, Great Lakes Naval Training Station, and Harry L. Baum, Denver.

Dr. William H. Johnston, Santa Barbara, Calif., read a paper on "Nasal Sinus Disease in Children; Its Diagnosis and Treatment." Discussed by Drs. Glenn J. Greenwood, Chicago; James M. Robb, Detroit; Burt R. Shurly, Detroit; Thomas E. Carmody, Denver; A. C. Hilding, Duluth, Minn.; O. E. Van Alyea, Chicago, and William H. Johnston, Santa Barbara, Calif.

Dr. Horace J. Williams, Philadelphia, read a paper on "The Use of Skin Graft in Tympanomastoidectomy." Discussed by Drs. John F. Delph, Chicago; William E. Grov, Milwaukee; Frederick Leaver Stauffer, Salt Lake City, and Horace J. Williams, Philadelphia.

THURSDAY, JUNE 15—MORNING

Executive Session

On motion by Dr. Gordon F. Harkness, Davenport, Iowa, seconded by Thomas E. Carmody, Denver, Edward J. Ryan, D.D.S., Evanston, Ill., was nominated for Associate Fellowship.

Dr. Louis H. Clerf, secretary, reported progress for the Advisory Committee of Council on Industrial Health, and the committee was instructed to continue its work.

Dr. Clerf reported progress for the Committee on Lye Legislation, and the committee was continued.

Dr. Claude C. Cody, the chairman, appointed Dr. W. E. Grove of Milwaukee as a candidate for the Board of Governors of the American College of Surgeons.

Dr. Clerf read a letter from the Argentine Society of Bronchoesophagoscopy, and the chairman instructed the incoming secretary to reply.

The following officers were elected: chairman, Dr. Louis H. Clerf, Philadelphia; vice chairman, Dr. Henry B. Orton, Newark, N. J.; secretary, Dr. Fletcher W. Woodward, Charlottesville, Va.; executive committee: Dr. Gordon F. Harkness, Davenport, Iowa; Dr. Claude C. Cody, Houston, Texas, and Dr. Louis H. Clerf, Philadelphia; delegate, Dr. Burt R. Shurly, Detroit; alternate, Dr. Gordon F. Harkness, Davenport, Iowa. Dr. LeRoy A. Schall, Boston, and Dr. John J. Shea, Memphis, Tenn., were appointed to the American Board of Otolaryngology.

A new gavel was presented to the section, and it was voted that the cost of the gavel be defrayed by the section.

Scientific Session

Dr. Claude C. Cody, Houston, Texas, read the chairman's address, entitled "Vitamin Therapy in Otolaryngology."

Dr. Marvin F. Jones, New York, read a paper on "Disturbed Vestibular Function: The Causes and Cures." Discussed by Drs. Lyle M. Sellers, Dallas, Texas; George E. Shambaugh Jr., Chicago, and Marvin F. Jones, New York.

Dr. Oram R. Kline, Camden, N. J., read a paper on "The Importance of Pathology of the Nasopharynx to the Otolaryngologist." Discussed by Drs. C. H. McCaskey, Indianapolis; Walter H. Theobald, Chicago; Barney M. Kully, Los Angeles, and Oram R. Kline, Camden, N. J.

Dr. Forrest W. Merica, Lakewood, Ohio, read a paper on "The Local Use of Sulfonamides in the Surgical Treatment in Diseases of the Ear."

Dr. Edward J. Whalen, Hartford, Conn., read a paper on "Sulfonamides in the Treatment of Nasal Sinus Disease."

These two papers were discussed by Drs. Ralph A. Fenton, Portland, Ore.; J. R. Lindsay, Chicago; M. M. Cullom, Nashville, Tenn.; H. W. Angell, Charleston, W. Va.; Claude C. Cody, Houston, Texas; Forrest W. Merica, Lakewood, Ohio, and Edward J. Whalen, Hartford, Conn.

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Ophthalmology. The proceedings are reported in the minutes of that section.

SECTION ON PEDIATRICS

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Hugh L. Dwyer, Kansas City, Mo.

Drs. Wallace S. Sako and W. L. Treuting, New Orleans, David B. Witt, Surgeon (R), U. S. P. H. S., and S. J. Nichamin, Surgeon (R), U. S. P. H. S., presented a paper on "The Early Immunization Against Pertussis." Discussed by Drs. Louis W. Sauer, Evanston, Ill., and Wallace S. Sako, New Orleans.

Dr. M. J. Shapiro, Minneapolis, read a paper on "The Pre-operative Diagnosis of Patent Ductus Arteriosus." Discussed by Drs. Leo G. Rigler, Minneapolis; Harry Vesell, New York, and M. J. Shapiro, Minneapolis.

Dr. Roger L. J. Kennedy, Rochester, Minn., read a paper on "Precocious Skeletal Development in Children." Discussed by Dr. John R. Vonachen, Peoria, Ill.

Dr. Oscar Reiss, Los Angeles, read a paper on "Mental Hygiene Aspects of Pediatrics." Discussed by Drs. Bert I. Beverly, Chicago; Ernst Wolff, San Francisco, and Oscar Reiss, Los Angeles.

Dr. J. Albert Key, St. Louis, read a paper on "Indications For and Evaluation Of Measures Used in the Treatment of Poliomyelitis." Discussed by Drs. Miland E. Kuapp, Minneapolis; John A. Toomey, Cleveland, and J. Albert Key, St. Louis.

Major Ralph H. Kunstadter, M. C., A. U. S., and Major Robert C. Pendergrass, M. C., A. U. S., presented a paper on

"Primary Coccidioidomycosis." Discussed by Major William H. Wood Jr., M. C., A. U. S.

On invitation of the chairman, Dr. Isaac Abt, Chicago, addressed the section.

THURSDAY, JUNE 15—AFTERNOON

The following papers were read as a symposium on "Abdominal Pain in Children":

Dr. Joseph Brennemann, Reading, Vt.: "The Pediatric View." Discussed by Drs. M. G. Peterman, Milwaukee; Joseph Golomb, New York, and Joseph Brennemann, Reading, Vt.

Dr. Bret Ratner, New York: "The Allergic View." Discussed by Drs. J. Victor Greenebaum, Cincinnati; W. Ambrose McGee, Richmond, Va., and Bret Ratner, New York.

Dr. Meredith F. Campbell, New York: "The Urologic View."

Dr. Alfred A. Strauss, Chicago: "The Surgical View."

These two papers were discussed by Drs. Herbert E. Coe, Seattle, and Ernst Wolff, San Francisco.

Dr. T. L. Terry, Boston, read a paper on "Ocular Maldevelopment in Extremely Premature Infants." Discussed by Drs. H. N. Sanford, Chicago; E. V. L. Brown, Chicago; A. J. Strich, Chicago, and T. L. Terry, Boston.

Dr. Victor Ross, New York, read a paper on "Preparation and Immunizing Properties of Protamine-Toxoid (Diphtheria)." Discussed by Dr. Ernest L. Stebbins, New York.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. John Aikman, Rochester, N. Y.; vice chairman, Dr. Henry G. Poncher, Chicago; secretary, Dr. Gilbert J. Levy, Memphis, Tenn.; delegate, Dr. William Weston, Columbia, S. C.; alternate, Dr. Julius H. Hess, Chicago; executive committee: Dr. Philip M. Stimson, New York; Dr. Hugh L. Dwyer, Kansas City, Mo., and Dr. John Aikman, Rochester, N. Y.; representative to Scientific Assembly, Dr. W. Ambrose McGee, Richmond, Va.

The following papers were read as a symposium on "Rheumatic Fever":

Dr. May G. Wilson, New York: "Recurrence Rates in Rheumatic Fever."

Dr. T. Duckett Jones, Boston: "Diagnosis of Rheumatic Fever."

Dr. David D. Rutstein, New York: "The Role of the Cardiac Clinic in the Rheumatic Fever Program."

Major A. C. H. van Ravenswaay, M. C., A. U. S.: "Geographic Factors in Acute Rheumatic Fever."

Dr. Caroline Bedell Thomas, Baltimore: "The Prevention of Recurrences in Rheumatic Fever Subjects."

These five papers were discussed by Drs. John R. Paul, New Haven, Conn.; Col. W. Paul Holbrook, M. C., A. U. S.; Drs. Stanley Gibson, Chicago; J. W. Scott, Lexington, Ky.; J. D. Keith, Nova Scotia; Paul F. Dwan, Minneapolis; May G. Wilson, New York; T. Duckett Jones, Boston; David D. Rutstein, New York; Major A. C. H. van Ravenswaay, M. C., A. U. S., and Dr. Caroline Bedell Thomas, Baltimore.

SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Tinsley R. Harrison, Dallas, Texas.

Drs. O. H. Robertson and Morton Hamburger Jr., Chicago, Capt. Clayton G. Loosli, M. C., A. U. S., Dr. Theodore T. Puck, Chicago, Lieut. Henry M. Lemon, M. C., A. U. S., and Dr. Henry Wise, Camp Carson, Colorado, presented a paper on "A Study of the Nature and Control of Air Borne Infection in Army Camps." Discussed by Drs. Edward Bigg, Evanston, Ill.; C. H. Rammelkamp, Fort Bragg, North Carolina; Francis G. Blake, New Haven, Conn., and Truman S. Potter, Chicago.

Dr. Lawrence W. Smith, Philadelphia, read a paper on "Wound Healing: An Experimental Study of Water Soluble

Chlorophyll) Derivatives in Conjunction with Various Antibacterial Agents." Discussed by Drs. Conrad R. Lam, Detroit; Lawrence W. Smith, Philadelphia, and Benjamin Gruskin, Chicago.

Drs. David Adlersberg and Henry Dolger, New York, presented a paper on "Insulin Mixtures in the Treatment of Diabetes: Variable versus Fixed Ratios of Insulin and Protamine Zinc Insulin." Discussed by Dr. Howard F. Root, Boston.

Dr. R. A. Woodbury, Augusta, Ga., and Lieut. P. H. Fried, M. C., A. U. S., presented a paper on "Influence of Neostigmine on Eclamptic Patients and Cholinesterase Activity of Normal and Preeclamptic Human Placentas." Discussed by Drs. A. R. Abarbanel, Washington, D. C.; J. Isfred Hofbauer, Cincinnati, and R. A. Woodbury, Augusta, Ga.

Lieut. Comdr. David H. Rosenberg (MC), U.S.N.R., and Lieut. P. A. Arling (MC), U.S.N.R., presented a paper on "Penicillin in the Treatment of Meningitis." Discussed by Dr. Wallace E. Herrell, Rochester, Minn., and Lieut. Comdr. David H. Rosenberg (MC), U.S.N.R.

Drs. Robert H. Williams and Howard M. Clute, Boston, presented a paper on "Thiouracil in the Treatment of Thyrotoxicosis." Discussed by Drs. W. O. Thompson, Chicago; Elmer C. Bartels, Boston; Karl E. Paschkis, Philadelphia; Rulon W. Rawson, Boston, and Robert H. Williams, Boston.

Drs. M. G. Fredricks and F. W. Hoffbauer, Minneapolis, presented a paper on "A Study of Liver Function in Therapeutic Malaria." Discussed by Drs. L. W. Diggs, Memphis, Tenn., and M. G. Fredricks, Minneapolis.

THURSDAY, JUNE 15—AFTERNOON

The following officers were elected: chairman, Dr. Edgar V. Allen, Rochester, Minn.; vice chairman, Dr. Carl A. Dragstedt, Chicago; secretary, Dr. Dwight L. Wilbur, San Francisco; delegate, Dr. Edgar V. Allen, Rochester, Minn.; alternate, Dr. C. M. Gruber, Philadelphia; in charge of exhibits, Dr. Robert W. Wilkins, Boston; executive committee: Dr. Wallace M. Yater, Washington, D. C.; Dr. Tinsley R. Harrison, Dallas, Texas, and Dr. Edgar V. Allen, Rochester, Minn.

The following papers were read as a symposium on "The Abuse of Rest in the Treatment of Disease":

Dr. Tinsley R. Harrison, Dallas, Texas: Chairman's address: "The Abuse of Rest as a Therapeutic Measure in Patients with Cardiovascular Disease."

Dr. Nicholson J. Eastman, Baltimore: "The Abuse of Rest in Obstetrics."

Dr. John H. Powers, Cooperstown, N. Y.: "The Abuse of Rest as a Means of Surgical Treatment: Early Postoperative Activity and Rehabilitation."

Dr. William Dock, Los Angeles: "The Evil Sequels of Complete Bed Rest."

Dr. Ralph K. Ghornley, Rochester, Minn.: "The Abuse of Rest as a Means of Treatment in Orthopedic Surgery."

Dr. Karl A. Menninger, Topeka, Kan.: "The Abuse of Rest as a Means of Treatment in Neuropsychiatry."

These six papers were discussed by Drs. J. Ross Veal, Washington, D. C.; Frank H. Krusen, Rochester, Minn.; H. Close Hesselstine, Chicago; Comdr. J. Murray Steel, Bethesda, Md.; Drs. D. J. Leithauser, Detroit; E. V. Allen, Rochester, Minn.; Don C. Sutton, Chicago; Louis N. Katz, Chicago; Nicholson J. Eastman, Baltimore; John H. Powers, Cooperstown, N. Y.; William Dock, Los Angeles; Karl A. Menninger, Topeka, Kan., and Tinsley R. Harrison, Dallas, Texas.

Dr. Frank H. Krusen, Rochester, Minn., read a paper on "The Future of Physical Medicine, with Special Reference to the Recommendations of the Baruch Committee on Physical Medicine."

FRIDAY, JUNE 16—AFTERNOON

A joint meeting was held with the Section on Practice of Medicine. The proceedings are reported in the minutes of that section.

SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:10 by the chairman, Dr. Frank C. Mann, Rochester, Minn.

The following were nominated for the American Board of Pathology: Dr. Nathan Chandler Foote, New York, to succeed himself; Dr. Shields Warren, Boston, to succeed Dr. Howard T. Karsner, Cleveland.

The following papers were read as a symposium on "Traumatic Shock":

Dr. Harold D. Green, Cleveland: "Traumatic Ischemic Shock, with Observations on Effects of Environmental Temperature."

Dr. Virgil H. Moon, Philadelphia: "Analysis of Traumatic Shock."

Dr. Joseph C. Aub, Boston: "A Toxic Factor in Traumatic Shock."

These three papers were discussed by Drs. Henry N. Harkins, Baltimore; Frederick M. Allen, New York; Benjamin Jablons, New York; Harold D. Green, Cleveland; Virgil H. Moon, Philadelphia, and Joseph C. Aub, Boston.

Dr. Charles A. Janeway, Boston, read a paper on "The Use of Albumin in Shock and Hypoproteinemias and of Gamma Globulin in Measles."

Dr. Franc D. Ingraham, Boston, read a paper on "The Use of Products of Fibrinogen and Thrombin in Surgery."

These two papers were discussed by Dr. Orville T. Bailey, Boston.

Dr. J. P. Quigley, Cleveland, and Lieut. D. A. Brody, M. C., A. U. S., presented a paper on "Pyloric Sphincter Motility and Its Relation to Gastric Evacuation and Other Phenomena." Discussed by Drs. Frank C. Mann, Rochester, Minn., and J. P. Quigley, Cleveland.

Drs. G. E. Wakerlin, M. L. Goldberg and Clarence A. Johnson, Chicago, presented a paper on "Treatment of Experimental Renal Hypertension with Renal Extracts." Discussed by Drs. Benjamin Jablons, New York, and G. E. Wakerlin, Chicago.

Drs. A. C. Ivy and A. J. Atkinson, Chicago, presented a paper on "The Influence of Caffeine Containing Beverages on Gastric Secretion and the Peptic Ulcer Problem." Discussed by Drs. Albert F. R. Andresen, Brooklyn; Theodore J. Curpley, Garden City, N. Y.; Heinrich Necheles, Chicago, and A. C. Ivy, Chicago.

THURSDAY, JUNE 15—MORNING

Dr. Frank C. Mann, Rochester, Minn., read the chairman's address, entitled "Hypoglycemia and Restoration with Dextrose."

Drs. Harry J. Corper and Manrice L. Cohn, Denver, presented a paper on "The Use of Diasone for the Treatment of Tuberculosis."

Dr. Israel Davidsohn, Chicago, read a paper on "The Diagnosis of Fetal Erythroblastosis." Discussed by Drs. A. G. Foord, Pasadena, Calif., and Israel Davidsohn, Chicago.

The following were nominated for Associate Fellowship: Dr. Béla Halpert, Oklahoma City, and Dr. Howard B. Lewis, Ann Arbor, Mich.

Drs. Roy R. Kracke, William R. Platt and A. M. Oshlag, Emory University, Ga., presented a paper on "Hematologic Problems in Syphilis." Discussed by Drs. Israel Davidsohn, Chicago; Frank W. Hartman, Detroit, and William R. Platt, Emory University, Ga.

Dr. Italo F. Volini, Chicago, Capt. Robert O. Levitt, M. C., A. U. S., and Major Richard R. Martin, M. C., A. U. S., presented a paper on "Sudden Death Due to Intravenous Injection in Mercurial Diuresis." Discussed by Drs. John W. Scott, Lexington, Ky., and Italo F. Volini, Chicago.

Dr Robert P Morehead, Winston Salem N C, read a paper on "Carcinoma in Young Persons Discussed by Capt J Edward Berk, Philadelphia, Drs F L Rector, Lansing, Mich, and Robert P Morehead, Winston-Salem, N C

Dr Tobias Weinberg, Baltimore, read a paper on "A Clinical and Pathologic Study of a Series of Renal Neoplasms"

A nominating committee was appointed consisting of Drs J P Simonds, Chicago, Henry J Cooper, Denver, and G E Wakerlin Chicago

FRIDAY, JUNE 16—MORNING

The following officers were elected chairman Dr Virgil H Moon, Philadelphia, vice chairman Dr J J Moore, Chicago, secretary, Dr Frank W Hartman Detroit delegate, Dr L W Larson, Bismarck, N D, alternate Dr H J Cooper, Denver, executive committee Dr J P Simonds, Chicago, Dr Frank C Mann, Rochester, Minn, and Dr Virgil H Moon, Philadelphia

On motion by Dr Virgil H Moon Philadelphia, a rising vote of thanks was given to Dr J J Moore Chicago for his many years of faithful service as secretary of the section

Dr Thomas Francis Jr, Ann Arbor Mich read a paper on "Physiologic Concepts of Virus Infections Discussed by Dr O H Robertson, Chicago

Surgeon Capt C H Best Bytown Ottawa Ontario Canada, read a paper on "Physiologic Contributions to War Medicine" Discussed by Drs Virgil H Moon Philadelphia Frederick M Allen, New York, Everett I Evans Richmond Va, and Surgeon Capt C H Best, Bytown Ontario Canada

Dr Henry N Harkins, Baltimore read a paper on "Recent Research in the Pathology of Burns Discussed by Drs Conrad R Lam, Detroit, H Perry Jenkins Chicago, Virgil H Moon Philadelphia, Everett I Evans Richmond Va, and Henry N Harkins, Baltimore

Lieut Carl C Pfeiffer, MC-V (S) USNR Ensign Lois F Hallman W-V (S) (H), USNR and Lieut I Gersh, H V (S) USNR, presented a paper on The Toxicity of Boric Acid as Applied to the Treatment of Burns Discussed by Drs Charles G Barnum, Groton, Conn Henry N Harkins, Baltimore, Lincoln Oppen, Norwich, Conn and Lieut Carl C Pfeiffer

Lieut Comdr G B Fauley (MC), USNR Lieut. T L Duggan (H-VS), USNR, and Lieut (jg) R T Stormont (MC), USNR presented a paper on Use of Penicillin in the Treatment of Peritonitis An Experimental Study

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr I M Nielsen, Los Angeles

Dr J M Nielsen, Los Angeles, read the chairman's address, entitled "Subacute Neuromuscular Exhaustion Syndrome"

Dr Henry R Viets, Boston, read a paper on "Myasthenia Gravis Discussed by Drs F G Lindemulder, San Diego, Calif and Henry R Viets, Boston

Drs Hans H Reese and Theodore C Erickson, Madison, Wis, presented a paper on "Musicogenic Epilepsy" Discussed by Drs Adrien Henri Verbruggen, Chicago, Lewis John Pollock, Chicago Joseph P Reich, Chicago C F Midelfart, Eau Claire, Wis, and Hans H Reese, Madison Wis

Drs Loyal Davis Frederick Hiller, George E Periet and Walter W Ca-toll, Chicago, presented a paper on "The Effect of Sulfonamide Drugs on Experimental Gunshot Wounds of Peripheral Nerves"

Dr Francis C Grant, Philadelphia, read a paper on "Epidural Spinal Abscess" Discussed by Drs Adrien H Verbruggen, Chicago, A W Adson, Rochester, Minn, George B Hassin, Chicago, and Francis C Grant Philadelphia

Dr C W Rucker, Rochester Minn, read a paper on "Sheathing of the Retinal Veins in Multiple Sclerosis Discussed by Drs Frederick P Moersch Rochester, Minn, R P Mackay, Chicago, and C W Rucker, Rochester, Minn

THURSDAY, JUNE 15—AFTERNOON

The following officers were elected chairman Dr Percival Bailey, Chicago, vice chairman, Dr H Houston Merritt, Boston, secretary, Dr R P Mackay, Chicago executive committee Dr T T Stone, Chicago, Dr A E Bennett Omaha, and Dr Henry Viets, Boston, delegate, Dr Henry Viets, Boston, alternate, Dr Joseph P Evans, Cincinnati representatives to American Board of Psychiatry and Neurology, Dr Hans H Reese, Madison, Wis, and Dr Walter Freeman Washington, D C, representative on Board of Neurosurgery, Dr Paul Bucy, Chicago, representative to Scientific Exhibit, Dr Frederick P Moersch, Rochester, Minn

Dr R P Mackay, Chicago, read the report of the Committee on Industrial Health, submitted by Dr T T Stone, chairman, which was accepted

Dr Walter Freeman, Washington, D C, gave a report from the American Board of Psychiatry and Neurology, which was accepted

Drs Raymond W Waggoner, Ann Arbor, Mich, Lieut Col William Menninger, M C, A U S, and Comdr Francis J Braceland (MC), USNR, presented a paper on "Psychiatric Selection of Men for the Armed Forces" Discussed by Dr Hans Deutsch, Chicago, Col Leonard G Rowntree M C, A U S, and Dr Raymond W Waggoner, Ann Arbor, Mich

Capt Jack G Sheps, R C A M C Toronto Ont, Canada, read a paper entitled "A Psychiatric Study of Successful Soldiers" Discussed by Lieut Col J D Griffin, R C A M C

A panel discussion on "Operational Fatigue in Combat Aircrews" was participated in by Lieut Col Roy R Gunker and Major Donald W Hastings M C, A U S, with Major William H Everts, M C, A U S, acting as moderator

Dr George N Thompson Jr, Los Angeles read a paper on "Neurophysiologic Improvements of Electrocortical Over Electroshock Therapy in Schizophrenia" Discussed by Drs Lloyd H Ziegler, Wauwatosa, Wis, John S Lundy, Rochester, Minn, J M Nielsen, Los Angeles, Meyer Solomon, Chicago, and George N Thompson Jr, Los Angeles

Drs Lothar B Kalmowsky, S E Barrera and W A Horwitz, New York, presented a paper on "The Question of Electric Convulsive Therapy in Psychoneuroses" Discussed by Drs Abram E Bennett, Omaha, Lloyd H Ziegler, Wauwatosa, Wis, V E Gonda, Chicago, Tom B Throckmorton, Des Moines, Iowa, Walter B Freeman, Washington, D C, and Lothar B Kalmowsky, New York

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Anesthesiology

Dr E S Gurdjian, Detroit, Major John E Webster, M C, A U S, and Dr W E Stone, Detroit, presented a paper on "Cerebral Metabolism in Experimental Head Injury" Discussed by Drs Francis G Grant, Philadelphia, Warren S McCulloch, Chicago, Percival Bailey, Chicago, and E S Gurdjian Detroit

Drs Perry P Volpitt and B E Abreu, Augusta, Ga, presented a paper on "The Influence of Different Forms of Artificial Respiration on the Pulmonary and Systemic Blood Pressure"

Dr Ralph M Waters, Madison, Wis, read a paper on "The Relation of Anesthesia to Hypoxia and Anoxia"

Dr Alfred D Biggs, Chicago, read a paper on "The Pediatric Aspects of Asphyxia Neonatorum"

Dr William F Windle, Chicago, presented a Motion Picture Demonstration on "Experimental Asphyxia Neonatorum"

Drs. Cyril B. Courville and B. Clemson Marsh, Los Angeles, presented a paper on "Neonatal Asphyxia: Some Observations on Its Neurologic and Neuropathologic Aspects."

These five papers were discussed by Drs. H. M. Livingstone, Chicago; W. H. Cassels, Chicago; William C. Danforth, Evans-ton, Ill.; Ben W. Lichtenstein, Chicago; R. P. Mackay, Chi-cago; Capt. W. Allen Conroy, Chicago; Drs. M. B. Rosenbluth, New York; Perry P. Volpito, Augusta, Ga.; Ralph M. Waters, Madison, Wis.; Alfred D. Biggs, Chicago; William F. Windle, Chicago, and B. Clemson Marsh, Los Angeles.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Clark W. Finnerud, Chicago.

Dr. Clark W. Finnerud read the chairman's address, entitled "Perleche: Its Nosologic Status."

Dr. George L. Clark, Urbana, Ill., read a paper on "The Electron Microscope in Dermatology." Discussed by Drs. Gregory Schwartzman, New York, and George L. Clark, Urbana, Ill.

Dr. Francis W. Lynch, St. Paul, read a paper on "Kaposi's Varicelliform Eruption: Extensive Herpes Simplex as a Complication of Eczema." Discussed by Drs. Oliver S. Ormsby, Chicago; Clinton W. Lane, St. Louis; Comdr. Marion B. Sulz-berger (MC), U.S.N.R.; Francis A. Ellis, Baltimore; M. H. Ebert, Chicago, and Francis W. Lynch, St. Paul.

Drs. George C. Andrews, Carl B. Braestrup and Eldred B. Heisel, New York, presented a paper on "The Exit Dose in Dermatologic Roentgen Therapy." Discussed by Drs. Harry R. Foerster, Milwaukee, and E. B. Heisel, New York.

Drs. Henry E. Michelson and Carl W. Laymon, Minneapolis, presented a paper on "A Classification of Tuberculosis of the Skin." Discussed by Drs. Ruben Nomland, Iowa City; Fred D. Weidman, Philadelphia; Hamilton Montgomery, Rochester, Minn.; Adolph Rostenberg, Washington, D. C.; Robert Brandt, Cincinnati, and Henry E. Michelson, Minneapolis.

Drs. Garold V. Stryker and William A. Halbeisen, St. Louis, presented a paper on "The Determination of Macrocytic Anemia as an Aid in the Diagnosis of Certain Deficiency Dermatoses." Discussed by Drs. Dudley C. Smith, Charlottesville, Va., and Garold V. Stryker, St. Louis.

THURSDAY, JUNE 15—AFTERNOON

The following officers were elected: chairman, Dr. Clyde Cummer, Cleveland; vice chairman, Dr. Dudley C. Smith, Charlottesville, Va.; secretary, Dr. Nelson P. Anderson, Los Angeles; chairman of exhibit, Dr. Hamilton Montgomery, Rochester, Minn.; delegate, Dr. Cornelius Ferd Lehmann, San Antonio, Texas; alternate, Dr. C. W. Lane, St. Louis; for two one year periods to succeed himself on the American Board of Dermatology and Syphilology, Dr. C. Guy Lane, Boston; to succeed himself for three one year periods on the American Board of Dermatology and Syphilology, Dr. Paul A. O'Leary, Rochester, Minn.

The following papers were read in a panel discussion on "Intensive Therapy of Early Syphilis, with Special Reference to Arsenotherapy Either Alone or Combined with Other Agents." Dr. Arthur G. Schoch, Dallas, Texas, moderator:

Dr. Harry Eagle, surgeon, U. S. P. H. S.: "The Treatment of Early and Latent Syphilis in Six to Twelve Weeks with Triweekly Injections of Mapharsen: An Analysis of the Results in the First 4,823 Cases."

Drs. A. Benson Cannon and Jerome K. Fisher, New York: "Intensive Arsenotherapy."

Dr. Evan W. Thomas, New York: "Combined Fever and Arsenotherapy in the Intensive Treatment of Early Syphilis."

These three papers were discussed by Drs. Herbert Rattner, Chicago; Charles M. Carpenter, Rochester, N. Y.; Paul T. Brieyere, Bethesda, Md.; Arthur C. Curtis, Ann Arbor, Mich.; George X. Schwemlein, Chicago; J. R. Driver, Cleveland; Roy L. Kile, Cleveland; Arthur G. Schoch, Dallas, Texas; Harry Eagle, Baltimore; Jerome K. Fisher, New York, and Evan W. Thomas, New York.

The following papers were read in a panel discussion on "Penicillin in the Treatment of Syphilis," Col. Udo J. Wile, U. S. P. H. S., moderator:

Drs. J. F. Mahoney, surgeon, R. C. Arnold, surgeon, and Ad Harris, serologist, U. S. P. H. S.: "Preliminary Results with Penicillin in Experimental Syphilis of Rabbits and in Early Syphilis of Human Beings."

Drs. Joseph Earle Moore, Baltimore; Lieut. Col. Thomas H. Sternberg, M. C., A. U. S.; Comdr. Walter H. Schwartz (MC), U.S.N.; John F. Mahoney, surgeon, U. S. P. H. S., and Dr. W. Barry Wood Jr., St. Louis: "The Preliminary Results of Penicillin Therapy in Early Syphilis in Human Beings with Varying Schemes of Treatment."

Drs. John H. Stokes, Philadelphia, and J. E. Moore, Balti-more; Lieut. Col. Thomas H. Sternberg, M. C., A. U. S.; Comdr. W. H. Schwartz (MC), U.S.N., and John F. Mahoney, surgeon, U. S. P. H. S.: "Preliminary Results of the Treatment of Late Syphilis with Penicillin."

These three papers were discussed by Lieut. Comdr. E. E. Barksdale (MC), U.S.N.R.; Capt. William Leifer, M. C., A. U. S.; Comdr. Frank A. Ellis, Corpus Christi, Texas; Col. Udo J. Wile, U. S. P. H. S., and Dr. Joseph E. Moore, Baltimore.

FRIDAY, JUNE 16—AFTERNOON

Dr. Hamilton Montgomery presented his report as repre-sentative to the Scientific Exhibit.

Dr. Richard Fowlkes reported for the Auditing Committee that the books were found to be in order and correct.

The chairman stated that Dr. Francis W. Lynch, St. Paul, had been selected as an assistant to Dr. Hamilton Montgomery as chairman of the Scientific Exhibit, beginning next year.

The report of the secretary of the American Board of Der-matology and Syphilology, Dr. C. Guy Lane, was received.

The report of the Committee on Industrial Dermatoses, Dr. Harry R. Foerster, Milwaukee, chairman, was received.

Dr. Francisco Ronchese, Providence, R. I., read a paper on "Calluses, Cicatrices and Other Stignias as an Aid in Estab-lishing Personal Identity." Discussed by Drs. Louis Schwartz, Bethesda, Md.; John G. Downing, Boston, and Maurice Oppen-heim, Chicago.

Drs. C. Guy Lane, Ethel M. Rockwood, Carl S. Sawyer and Irvin H. Blank, Boston, presented a paper on "Dermatoses of the Hands: Report of Study of 450 Consecutive Cases." Dis-cussed by Drs. Joseph V. Klauder, Philadelphia; Francis E. Seneear, Chicago; George C. Andrews, New York; Lloyd W. Ketron, Baltimore; Comdr. Marion B. Sulzberger (MC), U.S. N.R., and Dr. C. Guy Lane, Boston.

Dr. Harry J. Templeton, Oakland, Calif., read a paper on "Epidermal and Dermal Sensitization." Discussed by Drs. Edward A. Oliver, Chicago; Adolph Rostenberg, Washington, D. C.; Charles C. Dennie, Kansas City, Mo.; Howard Fox, New York, and John G. Downing, Boston.

Major Marion I. Davis, M. C., A. U. S., read a paper on "The Dermatologic Aspects of the Vesicant War Gases." Dis-cussed by Comdr. Robert L. Gilman (MC), U.S.N.R.; Charles C. Dennie, Kansas City, Mo.; Leon Goldman, Cincinnati; C. Guy Lane, Boston, and Major Marion I. Davis.

Drs. Hamilton Montgomery and Paul A. O'Leary, Roches-ter, Minn., presented a paper on "Nodular Vasculitis of the Extremities." Discussed by Drs. Michael H. Ebert, Chicago; John H. Lamb, Oklahoma City; F. D. Weidman, Philadelphia, and Hamilton Montgomery, Rochester, Minn.

Capt. Morris Waisman, M. C., A. U. S., read a paper on "Recurrent, Fixed Erysipelas-like Dermato-phylid."

SECTION ON PREVENTIVE AND
INDUSTRIAL MEDICINE AND
PUBLIC HEALTH

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Joseph W. Mountin, U. S. P. H. S., Washington, D. C.

On motion of Dr. Vlado A. Getting, Boston, seconded by Dr. Stanley H. Osborn, Hartford, Conn., the following resolution was adopted:

WHEREAS, The practice of and administration of public health has become a specialty within the practice of medicine for which more and more physicians are specially trained and in which they pursue lifetime careers, and

WHEREAS, The safeguarding and the improvement of the health of the people has always been a primary concern of the medical profession, and our responsibility in this field is so important that it has attracted and should continue to attract some of the ablest members of our profession; and

WHEREAS, Health officers have often devoted their lives to this field at the cost of considerable personal sacrifice, such as inadequate compensation, political interference, insecure tenure of office, lack of facilities for research or opportunities for personal advancement; and

WHEREAS, The American Medical Association has pointed out the fact that many sections of the country are without the benefit of full time trained health officers and that there is great need for more well trained physicians in this field; now therefore be it

Resolved, That (1) It is the considered opinion of this Association that full time health officers and other full time medical specialists in the public health field who have been specially trained for their highly important work should be compensated for their services in a manner comparable with the net professional income of the good surgeons or internists of the community;

(2) Adequate compensation and reasonable security in tenure of office will be necessary before physicians with proper qualifications to assume heavy responsibility of protecting and improving the health of the public will be available in sufficient number to meet the nation's existing needs.

On motion of Dr. W. W. Peter, New Haven, Conn., seconded by Dr. Gilbert G. Cottam, Pierre, S. D., the following resolution was adopted:

WHEREAS, It appears that the problem of tuberculosis control is one that is increased in time of war, and

WHEREAS, Tuberculosis is no respecter of geographic boundaries, and the problem of supervision and care of the migratory, tuberculous families is becoming more acute as a result of the mass movement of populations at the present time, and may be anticipated to be even greater in the period of industrial conversion; and

WHEREAS, The number of tuberculous veterans of the armed forces is anticipated as an additional burden to the control machinery; and

WHEREAS, Existing public and private health facilities are already overtaxed; and

WHEREAS, A method of implementation and extension of the tuberculosis control work of the United States Public Health Service has been made in the form of H. R. 4615 and S. 1851 for Congressional action and appropriation, approved by the National Tuberculosis Association; and

WHEREAS, The State and Territorial Health Officers Association strongly urged the passage of such legislation; and

WHEREAS, The tuberculosis committee of the Missouri State Medical Association has approved this legislation, and the house of delegates of the Missouri Medical Association has also approved the legislation and has instructed its delegates to the American Medical Association to present these bills to the House of Delegates of the American Medical Association; and

WHEREAS, The Council of the Medical and Chirurgical Faculty of Maryland adopted a resolution endorsing H. R. 4615 and S. 1851 and urged the passage of this legislation; therefore be it

Resolved, That the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association at its annual meeting in Chicago, on June 12-16, 1944 approve Senate Bill 1851 and House of Representatives Bill 4615 and urge the Congress of the United States to enact these bills into law.

Dr. L. E. Himler, Ann Arbor, Mich., read a paper on "Psychiatric Technics in the Employment of Disabled Ex-Servicemen"

Mr. W. P. Jacobs, Clinton, S. C., read a paper on "Physical Fitness in Industry." Discussed by Dr. W. A. Sawyer, Rochester, N. Y.; Col. L. G. Rowntree, Washington, D. C., and Drs. Carl A. Wilzbach, Cincinnati; Kingsley Roberts, New York; Irving Gray, Brooklyn; Morris Raskin, Detroit, and R. B. Crain, Rochester, N. Y.

Drs. W. A. Sodeman and R. L. Pullen, New Orleans, presented a paper on "Bagasse Disease of the Lungs." Discussed by Drs. H. T. Engelhardt, New Orleans; Irving Gray, Brooklyn, and W. A. Sodeman, New Orleans.

Dr. Bruno Gebhard, Cleveland, read a paper on "Community Health Education by the Medical Profession." Discussed by Drs. W. W. Bauer, Chicago; Emery R. Hayhurst, Columbus, Ohio; Charles V. Craster, Newark, N. J.; Mr. Homer Calver, New York, and Dr. Bruno Gebhard, Cleveland.

Dr. Joseph W. Mountin, U. S. P. H. S., Washington, D. C., read the chairman's address, entitled "Relocating of Physicians as Prerequisite to Better Medical Service."

THURSDAY, JUNE 15—MORNING

On motion of Dr. Carl A. Wilzbach, Cincinnati, duly seconded, the following resolution was adopted:

WHEREAS, High ranking officials of the various branches of our armed forces have stressed the importance of physical fitness in the war effort; and

WHEREAS, The American Medical Association has endorsed the Physical Fitness Program for High Schools as sponsored by the U. S. Department of Education; and

WHEREAS, Physical fitness was emphasized again at the meeting of the Section on Preventive and Industrial Medicine and Public Health on June 14, 1944; now therefore be it

Resolved, That the Section on Preventive and Industrial Medicine and Public Health recommend to the Council on Industrial Health that it endorse and where possible assist in the efforts for providing physical fitness for all workers in industry as a means of increasing the production of war materials and for the general improvement of health; and be it further

Resolved, That the Council on Industrial Health request official approval of the American Medical Association for this action.

The following papers were read in a panel discussion on "Variations in Industrial Medical Service Plans":

Dr. James M. Adams, New York: "Stanocola Medical Care Plan."

Dr. M. S. Bloom, Binghamton, N. Y.: "Variations in Current Industrial Medical Service Plans."

Dr. Sidney R. Garfield, Oakland, Calif.: "Health Plan Principles in the Kaiser Industries"

Dr. Edward M. Jones, Johnson City, N. Y.: "Endicott-Johnson Medical Plan."

Dr. James C. McCann, Worcester, Mass.: "Medical Society Prepayment Programs: Lessons Learned from Experience in Massachusetts."

Dr. John J. Wittmer, New York: "Variations in Current Industrial Medical Service Plans."

After a question and answer period these six papers were discussed by Drs. Dean A. Clark, U. S. P. H. S., Washington, D. C.; Francis M. Pottenger, Monrovia, Calif.; Kingsley Roberts, New York; Charles V. Craster, Newark, N. J.; David A. McCoy, Boston; C. Rufus Rorem, Chicago; James C. McCann, Worcester, Mass.; James M. Adams, New York; M. S. Bloom, Binghamton, N. Y.; Sidney R. Garfield, Oakland, Calif.; Edward M. Jones, Johnson City, N. Y., and John J. Wittmer, New York.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. E. L. Stebbins, New York; vice chairman, Dr. C. O. Sappington, Chicago; secretary, Dr. W. A. Sawyer, Rochester, N. Y.; executive committee: Dr. Haven Emerson, New York; Dr. Joseph W. Mountin, U. S. P. H. S., Washington, D. C., and Dr. E. L. Stebbins, New York; delegate, Dr. Stanley H. Osborn, Hartford, Conn.; alternate, Dr. Leverett Dale Bristol, New York.

Dr. Arthur Massey, Coventry, England, Honor Guest, gave an address entitled "Recent Developments in British Health Service." Discussed by Drs. Gilbert G. Cottam, Pierre, S. D.; Reginald M. Atwater, New York; Carl A. Wilzbach, Cincinnati; Marshall W. Meyer, Green Bay, Wis.; Felix J. Underwood, Jackson, Miss., and Arthur Massey, Coventry, England.

Dr. Carl A. Wilzbach read a paper on "Report on Medical and Dental Examinations of 6,000 High School Boys and Girls." Discussed by Col. L. G. Rowntree, M. C., A. U. S., Washington, D. C., and Drs. R. B. Crain, Rochester, N. Y.; Emery R. Hayhurst, Columbus, Ohio; A. A. Peter, New Haven, Conn.; F. L. Rector, Lansing, Mich.; Bernard A. Schwartz, Cincinnati, and Carl A. Wilzbach, Cincinnati.

Dr. David M. Gould, U. S. P. H. S., Bethesda, Md., read a paper on "Nontuberculous Lesions Found in Mass X-Ray

Surveys." Discussed by Drs. Russell H. Morgan, Chicago; Joseph W. Mountin, U. S. P. H. S., Washington, D. C.; R. B. Crain, Rochester, N. Y.; Marshall W. Meyer, Green Bay, Wis., and David M. Gould, U. S. P. H. S., Bethesda, Md.

Drs. Haven Emerson and Reginald M. Atwater, New York, presented a paper on "National Health Based on Local Health Units." Discussed by Drs. Richard F. Boyd, Springfield, Ill.; Felix J. Underwood, Jackson, Miss.; Gilbert G. Cottam, Pierre, S. D.; James R. Scott, Santa Fe, N. M.; Joseph W. Mountin, U. S. P. H. S., Washington, D. C., and Reginald M. Atwater, New York.

SECTION ON UROLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:15 by the chairman, Comdr. Gershom J. Thompson (MC), U.S.N.R.

Drs. J. Sydney Ritter and Samuel E. Kramer, New York, presented a paper on "Ureterovesical Obstruction."

Dr. Samuel A. Vest, Charlottesville, Va., read a paper on "A New Inspection Lens-Sheath as an Aid to Transurethral Resection."

These two papers were discussed by Dr. John H. Morrissey, New York.

The following papers were read as a symposium on "The Treatment of Cancer of the Prostate Gland":

Dr. William P. Herbst, Washington, D. C.: "Effects of Biochemical Therapeutics in Cancer of the Prostate Gland: Further Observation."

Drs. Gordon F. Moore, Carl A. Wattenberg and D. K. Rose, St. Louis: "Breast Changes Due to Diethylstilbestrol During Treatment of Cancer of the Prostate Gland."

Drs. John L. Enmett and Laurence F. Greene, Rochester, Minn.: "Clinical Experience with Bilateral Orchiectomy for Carcinoma of the Prostate Gland."

Dr. J. A. C. Colston, Baltimore: "Surgical Removal of Cancer of the Prostate Gland: The Radical Operation."

Drs. H. C. Bumpus Jr., Ben D. Massey and Earl F. Nation, Pasadena, Calif.: "Experiences with Orchiectomy for Carcinoma of the Prostate Gland."

These five papers were discussed by Drs. Robert H. Cummings, Ann Arbor, Mich.; Walter M. Kearns, Milwaukee; A. Elmer Belt, Los Angeles; N. G. Alcock, Iowa City; Henry K. Sangree, Philadelphia; Victor D. Lespinasse, Chicago, and William P. Herbst, Washington, D. C.

THURSDAY, JUNE 15—MORNING

The following officers were elected: chairman, Dr. Arbor D. Munger, Lincoln, Neb.; vice chairman, Lieut. Col. Lloyd G. Lewis, Washington, D. C.; secretary, Dr. Grayson L. Carroll, St. Louis.

The secretary read the report of the American Board of Urology.

Drs. Edwin L. Prien and Clifford Frondel, Boston, presented a paper on "Analysis of Urinary Calculi by Methods of Optical and X-Ray Crystallography." Discussed by Drs. Anson L. Clark, Oklahoma City, and Edwin L. Prien, Boston.

Comdr. James C. Sargent (MC), U.S.N.R., read a paper on "The Seminal Vesiculogram: An Effort at Interpretation."

Drs. M. Leopold Brodny and Samuel A. Robins, Boston, presented a paper on "Enuresis: The Use of the Urethrogram in Diagnosis."

These two papers were discussed by Drs. George H. Ewell, Madison, Wis.; Lieut. Col. Dorrin F. Rudnick, M. C., U. S. Army; R. E. Van Dusen, Dallas, Texas; Grayson L. Carroll, St. Louis; Meredith F. Campbell, New York, and M. Leopold Brodny, Boston.

Dr. Oswald S. Lowsley, New York, and Lieut. Comdr. Mark S. Curtis (MC), U.S.N.R., presented a paper on "The Surgical Aspects of Cystic Diseases of the Kidney." Discussed by Drs.

William F. Braasch, Rochester, Minn., and George R. Livermore, Memphis, Tenn.

Lieut. Col. Lloyd G. Lewis, M. C., A. U. S., read a paper on "The Urologic Treatment After Spinal Injury." Discussed by Dr. Arbor D. Munger, Lincoln, Neb.

Comdr. Gershom J. Thompson (MC), U.S.N.R., read the chairman's address, entitled "The Clinical Use of Penicillin in Genitourinary Infections."

Drs. Elmer Hess, Erie, Pa., and B. W. Wright, Nashville, Tenn., presented a paper on "Pyelocystanastomosis: Report of Two Cases." Discussed by Drs. Edgar Burns, New Orleans; B. W. Wright, Nashville, Tenn., and N. G. Alcock, Iowa City.

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Obstetrics and Gynecology. The proceedings are reported in the minutes of that section.

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Guy A. Caldwell, New Orleans.

Major Claude N. Lambert, M. C., A. U. S., read a paper on "Delayed Healing Time of Fractures at High Altitudes." Discussed by Col. Grover Penberthy, M. C., A. U. S.; Lieut. Col. A. R. Shands Jr., M. C., A. U. S.; Drs. D. B. Phemister, Chicago; Theodore A. Willis, Cleveland; J. Albert Key, St. Louis, and H. D. Corbusier, New Mexico, and Major Claude N. Lambert, M. C., A. U. S.

Major James J. Callahan, M. C., A. U. S., read a paper on "Revascularization of Carpal Bones." Discussed by Drs. Kellogg Speed, Chicago; D. B. Phemister, Chicago, and Major James J. Callahan.

The following were appointed as a nominating committee: Drs. J. E. M. Thomson, Lincoln, Neb., chairman; Harold B. Boyd, Memphis, Tenn., and Walter G. Stuck, San Antonio, Texas.

Dr. Roy I. Peck, Philadelphia, read a paper on "Treatment of Skeletal Metastases in Prostatic Carcinoma." Discussed by Drs. J. Albert Key, St. Louis; Elmer Hess, Erie, Pa., and Roy I. Peck, Philadelphia.

Dr. G. Edmund Haggart, Boston, read a paper on "Degenerative Arthritis of the Hip Joint Treated by One and Two Stage Arthrodesis with Metal Fixation." Discussed by Drs. David M. Bosworth, New York; Herman C. Schumm, Milwaukee; J. Warren White, Greenville, S. C.; Walter P. Blount, Milwaukee, and G. Edmund Haggart, Boston.

Dr. James Archer O'Reilly, St. Louis, gave a report from the House of Delegates.

Drs. W. H. Bickel, Rochester, Minn., and J. J. Hinchey, St. Paul, presented a paper on "One Stage Combined Rib Resection and Spinal Fusion for Severe Scoliosis." Discussed by Drs. Edward L. Compere, Chicago; Daniel H. Levinthal, Chicago, and W. H. Bickel, Rochester, Minn.

Dr. Harold B. Boyd, Memphis, Tenn., read a paper on "Fractures of the Elbow in Children." Discussed by Drs. John Dinnlop, Pasadena, Calif.; J. Warren White, Greenville, S. C.; Walter P. Blount, Milwaukee, and Harold B. Boyd, Memphis.

THURSDAY, JUNE 15—MORNING

Drs. J. Warren White and Sam G. Stubbins, Greenville, S. C., read a paper on "Growth Arrest for Equalizing Leg Lengths." Discussed by Drs. Sylvan L. Haas, San Francisco; C. Howard Hatcher, Chicago, and J. Warren White, Greenville, S. C.

Dr. Guy A. Caldwell, New Orleans, read the chairman's address, entitled "The Postwar Challenge to Orthopedic Surgery."

Dr. Eben J. Carey, Milwaukee, read a paper on "The Pathology of Motor End Plates in Skeletal Muscle, with Special Emphasis on Poliomyelitis."

Dr. Ralph K. Ghormley, Rochester, Minn., presented a report for the Committee for Investigation of Kenny Treatment of Poliomyelitis. Supplemental reports were presented by Drs. J. Albert Key, St. Louis, and Edward L. Compere, Chicago.

Surg. Gen. Norman T. Kirk addressed the section.

The following officers were elected: chairman, Dr. Theodore A. Willis, Cleveland; vice chairman, Lieut. Col. Francis M. McKeever, M. C., A. U. S., Los Angeles; secretary, Dr. J. Warren White, Greenville, S. C.; executive committee: Dr. J. A. Dickson, Cleveland, Dr. Guy A. Caldwell, New Orleans, and Dr. Theodore A. Willis, Cleveland; delegate, Dr. James Archer O'Reilly, St. Louis; alternate, Dr. Herman C. Schumm, Milwaukee; members of Board of Examiners of Orthopedic Surgery: Dr. Robert D. Schrock, Omaha, and Dr. G. Edmund Haggart, Boston.

Dr. Harrison L. McLaughlin, New York, read a paper on "Lesions of the Musculotendinous Cuff of the Shoulder: Differential Diagnosis of Rupture." Discussed by Drs. James E. M. Thomson, Lincoln, Neb.; Edwin W. Ryerson, Chicago, and Harrison L. McLaughlin, New York.

Dr. William T. Green, Boston, read a paper on "Slipping of the Upper Femoral Epiphysis: Diagnostic and Therapeutic Considerations." Discussed by Drs. Fremont A. Chandler, Chicago; Walter P. Blount, Milwaukee; J. Warren White, Greenville, S. C., and William T. Green, Boston.

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Radiology.

Major Gilbert W. Heublein, M. C., A. U. S., read a paper on "X-Ray Considerations of Traumatic Lesions of the Cervical Spine."

Dr. Arthur G. Davis, Erie, Pa., read a paper on "The Clinical Diagnosis, Treatment and Prognosis of Traumatic Lesions of the Cervical Spine." Discussed by Drs. John Dunlop, Pasadena, Calif.; R. K. Ghormley, Rochester, Minn., and Frank R. Ober, Boston.

Dr. Howard P. Doub, Detroit, read a paper on "Roentgen Studies of Aseptic Necrosis of the Epiphyses and Short Bones."

Dr. Wallace H. Cole, St. Paul, read a paper on "The Clinical Diagnosis, Treatment and Prognosis of Epiphyseal Disturbances in Childhood." Discussed by Drs. Frank R. Ober, Boston; W. Edward Chamberlain, Philadelphia, and D. B. Phemister, Chicago.

Dr. John W. Pierson, Baltimore, and Lieut. Comdr. John F. Roach (MC), U.S.N., presented a paper entitled "The Roentgenology of Osteomyelitis."

Dr. Frank D. Dickson, Kansas City, Mo., read a paper on "The Clinical Diagnosis, Treatment and Prognosis of Acute Hematogenous Osteomyelitis." Discussed by Drs. E. E. Mansur, Jefferson City, Mo., and Carl Badgley, Ann Arbor, Mich.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Emmett H. Terrell, Richmond, Va.

Drs. Lester M. Morrison and Ernest A. Spiegel, Philadelphia, presented a paper on "Demonstration of Visceral Pain by Determination of Skin Potentials." Discussed by Drs. Francis M. Pottenger, Monrovia, Calif.; Jose Mendez Feros, Havana, Cuba, and Lester M. Morrison, Philadelphia.

Dr. Frank C. Yeomans, New York, read a paper on "Sigmoidoscopy in Diagnosis and Treatment." Discussed by Drs. Descum C. McKenney, Buffalo; C. C. Tucker, Wichita, Kan., and Frank C. Yeomans, New York.

Dr. Frank W. Hartman, Detroit, read a paper on "Curling's Ulcer in Experimental Burns." Discussed by Drs. T. E. Bratrud, Minneapolis, and Frank W. Hartman, Detroit.

Drs. Russell S. Boles, Helena E. Riggs and John G. Reinhold, Philadelphia, presented a paper on "Observations on the Chemical Composition of the Blood and on Some Cardiovascular Reactions in Chronic Peptic Ulcer Throughout One Year." Discussed by Drs. Heinrich Necheles, Chicago, and Russell S. Boles, Philadelphia.

Dr. Everett N. Collins, Cleveland, read a paper on "The Use of Aluminum Hydroxide and Other Nonabsorbable Antacids in the Treatment of Peptic Ulcer." Discussed by Drs. James Flexner, New York; Walter L. Palmer, Chicago, and Everett N. Collins, Cleveland.

Dr. Benjamin M. Bernstein, Brooklyn, read a paper on "Gastroduodenal Dyssynergia." Discussed by Drs. Walter C. Alvarez, Rochester, Minn.; Walter L. Palmer, Chicago; Sara M. Jordan, Boston, and Benjamin M. Bernstein, Brooklyn.

Drs. Martin G. Vorhaus and S. Zachary Orgel, New York, presented a paper on "Psychosomatic Factors in Gastrointestinal Disorders." Discussed by Drs. Franz G. Alexander, Chicago; Sidney A. Portis, Chicago; Benjamin M. Bernstein, Brooklyn; George B. Eustermann, Rochester, Minn., and S. Zachary Orgel, New York.

Dr. Henry A. Rafsky, New York, read a paper on "Medical War Problems Confronting the Civilian Physician Today." Discussed by Major Jerome S. Levy, M. C., A. U. S.; Capt. J. Edward Berk, M. C., A. U. S., Utica, N. Y., and Henry A. Rafsky, New York.

THURSDAY, JUNE 15—AFTERNOON

The following officers were elected: chairman, Dr. J. Arnold Barga, Rochester, Minn.; vice chairman, Dr. Martin S. Kleckner, Allentown, Pa.; secretary, Dr. Sara M. Jordan, Boston; executive committee: Dr. Walter L. Palmer, Chicago; Dr. Emmett H. Terrell, Richmond, Va., and Dr. J. Arnold Barga, Rochester, Minn.; delegate, Dr. Louis A. Buie, Rochester, Minn.; alternate, Dr. Walter L. Palmer, Chicago; chairman of scientific exhibit, Dr. Grant H. Laing, Chicago; member certifying committee, Board of Proctology, Dr. Frank C. Yeomans, New York.

Dr. Emmett H. Terrell, Richmond, Va., read the chairman's address, entitled "Present Day Proctology."

Dr. Paul C. Blaisdell, Pasadena, Calif., read a paper on "Traumatic Injuries of the Rectum." Discussed by Drs. Malcolm R. Hill, Los Angeles, and Paul C. Blaisdell, Pasadena, Calif.

Dr. Curtice Rosser, Dallas, Texas, read a paper on "Benign Surgical Lesions of the Right Colon." Discussed by Dr. Walter A. Fansler, Minneapolis.

Drs. W. Wayne Babcock and Harry E. Bacon, Philadelphia, presented a paper on "Complications in the Operative Treatment of Cancer of the Colon."

Dr. Moses Behrend, Philadelphia, read a paper on "Colon Surgery and the Sulfonamide Drugs, with Especial Reference to the Elimination of the Mikulicz Operation."

Dr. Edward G. Martin, Detroit, read a paper on "Resistance: The Function of the Colon." Discussed by Dr. Joseph Felsen, New York.

Dr. Paul B. Welch, Miami, Fla., read a paper on "Distortions of the Gastric Feeding Reflex Associated with Extragastric Pathology: Their Clinical Significance." Discussed by Drs. Morton J. Oppenheimer, Philadelphia, and Paul B. Welch, Miami, Fla.

Dr. Everett D. Kiefer, Boston, read a paper on "Criteria in the Management of Chronic Ileitis." Discussed by Drs. J. Arnold Barga, Rochester, Minn.; Henry A. Rafsky, New York, and Everett D. Kiefer, Boston.

Drs. Harry L. Segal and W. J. Merle Scott, Rochester, N. Y., presented a paper on "Small Intestinal Lesions Producing Mas-

sive Hemorrhage and Symptoms Simulating Peptic Ulcer." Discussed by Drs. T. E. Jones, Cleveland, and Stockton Kimball, Buffalo.

Drs. Daniel N. Silverman and Alan N. Leslie, New Orleans, presented a paper on "Intractable Amebic Colitis." Discussed by Drs. Walter L. Palmer, Chicago; M. G. Spiesman, Chicago, and Daniel N. Silverman, New Orleans.

Dr. Joseph Felsen, New York, read a paper on "Bacillary Dysentery in War." Discussed by Drs. Herman M. Pollard, Ann Arbor, Mich.; Daniel N. Silverman, New Orleans, and Joseph Felsen, New York.

FRIDAY, JUNE 16—AFTERNOON

A joint meeting was held with the Section on Surgery, General and Abdominal.

Dr. A. H. Aaron, Buffalo, read a paper on "Inflammatory Lesions of the Stomach and Duodenum: Medical Aspect."

Dr. Frank H. Lahey, Boston, read a paper on "Inflammatory Lesions of the Stomach and Duodenum: Surgical Aspect."

These two papers were discussed by Drs. Albert F. R. Andresen, Brooklyn; Marie Ortmayer, Chicago; Henry A. Rafsky, New York; Sara M. Jordan, Boston; A. H. Aaron, Buffalo, and Frank H. Lahey, Boston.

Dr. Henry L. Bockus, Philadelphia, read a paper on "Inflammatory Lesions of the Small Intestine: Medical Aspect."

Dr. Henry W. Cave, New York, read a paper on "Inflammatory Lesions of the Small Intestine: Surgical Aspect."

These two papers were discussed by Drs. Burrill B. Crohn, New York; Marie Ortmayer, Chicago, and Henry W. Cave, New York.

Dr. J. Arnold Bergen, Rochester, Minn., read a paper on "Inflammatory Lesions of the Colon: Medical Aspect."

Dr. Thomas E. Jones, Cleveland, read a paper on "Inflammatory Lesions of the Colon: Surgical Aspect."

These two papers were discussed by Drs. Donovan C. Browne, New Orleans; Raymond W. McNealy, Chicago; M. H. Streicher, Chicago; J. Arnold Bergen, Rochester, Minn., and Thomas E. Jones, Cleveland.

SECTION ON RADIOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Robert A. Arens, Chicago.

Drs. Frederick E. Templeton and Paul M. Moore, Cleveland, presented a paper on "Cardiospasm: A Roentgenologic Study of Muscular Action." Discussed by Dr. A. M. Olsen, Rochester, Minn.

Drs. Leo G. Rigler and Henry S. Kaplan, Minneapolis, and Capt. Daniel L. Fink, M. C., A. U. S., presented a paper on "Pernicious Anemia and Tumors of the Stomach." Discussed by Drs. Harry Weber, Rochester, Minn.; Paul Swenson, Philadelphia, and Peter Casellas, San Juan, Puerto Rico.

Drs. Arthur P. Ehternacht and John Alexander Campbell, Indianapolis, presented a paper on "The Value of Scout Films of the Abdomen." Discussed by Dr. Leroy Sante, St. Louis.

Dr. Hugh F. Hare, Boston, read a paper on "Osteitis Condensans Ilii."

Capt. Charles F. Berens (MC), U.S.N.R., read a paper on "Some Radiologic Considerations of Upper Extremity Pain."

THURSDAY, JUNE 15—AFTERNOON

The chairman announced the death of the secretary of the section, Dr. John T. Murphy of Toledo, that morning, and the members arose and stood in silent tribute to his memory.

The following officers were elected: chairman, Dr. Edwin C. Ernst, St. Louis; vice chairman, Dr. Bernard P. Widmann, Philadelphia; secretary, Dr. U. V. Portmann, Cleveland; delegate, Dr. B. R. Kirkland, Rochester, Minn.; alternate, Dr.

Eugene Pendergrass, Philadelphia; delegate to the American Board of Radiology, Dr. John W. Picerson, Baltimore.

Dr. Robert A. Arens, Chicago, read the chairman's address, entitled "Radiologic Aspects of the Urologic Problem."

Drs. Harry H. Bowing and Robert E. Fricke, Rochester, Minn., read a paper on "Urinary Complications in Cases of Carcinoma of the Uterine Cervix: Management and Prognosis." Discussed by Dr. Edward Earl Mansur, Jefferson City, Mo.

Dr. C. D. Selby, Detroit, read a paper on "Industry's Attitude Toward X-Ray Examination of the Chest." Discussed by Col. A. J. Lanza, M. C., A. U. S.

Drs. Eugene P. Pendergrass and Simon S. Leopold, Philadelphia, presented a paper on "Benign Pneumonoconiosis." Discussed by Col. A. J. Lanza, M. C., A. U. S.; Dr. I. S. Trostler, Chicago, and Dr. Norbert Enzer, Milwaukee.

Dr. Richard E. Kinzer, M. C., A. U. S., read a paper on "An Analysis of Disqualifying Conditions Found During the Chest X-Ray Examination of 105,141 Selectees." Discussed by Drs. Robert G. Bloch, Chicago, and Capt. H. J. Prichard, Chicago.

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Orthopedic Surgery. The proceedings are reported in the minutes of that section.

SECTION ON ANESTHESIOLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:15 by the chairman, Dr. Paul M. Wood, New York.

Dr. Henry S. Ruth, Merion Station, Pa., read a paper on "Anesthesia Study Commissions." Discussed by Drs. Frederick P. Haugen, Philadelphia, and Roland J. Whitacre, East Cleveland, Ohio.

Dr. Urban H. Eversole, Boston, read a paper on "Why Use Spinal Anesthesia?"

Dr. Edward B. Tuohy, M. C., A. U. S., read a paper on "Continuous Spinal Anesthesia: Its Usefulness and the Technique Involved."

These two papers were discussed by Drs. William T. Lemmon, Philadelphia, and Capt. Floyd T. Romberger, M. C., A. U. S.

Dr. Harold R. Griffith, Montreal, read a paper on "Curarc." Discussed by Drs. Stuart C. Cullen, Iowa City, and J. W. Baird, Minneapolis.

WEDNESDAY, JUNE 14—MORNING

Business Session

The secretary, Dr. John S. Lundy, Rochester, Minn., read a letter from Dr. L. H. Bauer, chairman of the Council on Medical Service and Public Relations, and a letter from Dr. James R. Miller, Hartford, Conn., addressed to Dr. Bauer, regarding the demand from the public that charges for diagnostic x-ray examinations be combined in the total hospital bill along with charges for anesthesiology and laboratory services. The matter was referred to the executive committee, which prepared instructions for the delegate to the House:

1. It is the opinion of the committee, confirmed by the section, that anesthesiology is the practice of medicine; that medical practice is distinct from hospital service and must so remain.
2. It is the opinion of this body that services rendered patients by medical anesthesiologists, regardless of economic arrangement, is one of responsibility and has and always must maintain close personal relationship of patient and physician.

It was moved, seconded and unanimously carried to accept these instructions to the delegate to the House.

Dr. Henry S. Ruth, Merion Station, Pa., the representative of the section in the House of Delegates, reported on a resolution presented at the meeting of the House, recommending that the American Medical Association commend and encourage 1911 as the centenary year of Horace Wells's first application of

nitrous oxide as an agent for inhalation of anesthesia. After considerable discussion as to the wording of the resolution, it was unanimously moved to lay the resolution on the table until the meeting of the section on the following morning, to permit the wording of the resolution to meet the approval of the section. It was agreed that Dr. Curtis B. Hickox, Hartford, Conn., would reword the resolution.

Major Harold Bishop, Washington, D. C., offered a resolution that a representative of the section be appointed to present the matter of anesthesia study commissions and their importance to the executive committee of the American Medical Association with a view to possible adoption in its educational program so that it could be put on a national scale.

Dr. Walters asked Major Bishop to change the motion to the effect that the chairman be asked to appoint a committee of three to consider this matter and present it at the next business session. Major Bishop accepted the change, and the motion was seconded and carried. Major Bishop, Dr. Haugen and Dr. Whitacre were appointed to meet with the executive committee concerning this resolution.

THURSDAY, JUNE 15—MORNING

The following officers were elected: chairman, Dr. Ansel M. Caine, New Orleans; vice chairman, Dr. Harold C. Kelley, New York; secretary, Dr. John S. Lundy, Rochester, Minn.; delegate, Dr. Henry S. Ruth, Philadelphia; alternate, Dr. H. Boyd Stewart, Tulsa, Okla.

Major Harold Bishop reported for the committee of three on the matter of anesthesia study commissions appointed at the preceding meeting (resolution taken by Dr. Ruth for presentation to the House of Delegates).

Dr. Lundy read the letter drafted in reply to Dr. L. H. Bauer:

Your letter with enclosure to Dr. John S. Lundy, secretary of the Section on Anesthesiology, under date of Jan. 20, 1944, has been considered by the executive committee of the section.

The committee, after due deliberation, concurs in the following reply.

1. We feel that the proper practice of anesthesiology involves personal relationship between physicians and patients no less intimate than that enjoyed by a majority of medical practitioners.

2. Past experience indicates that the destruction of such personal relationship tends to jeopardize the best professional service to patients.

3. Evidence tends to show that the employment of anesthesiologists by hospitals on a salary basis rarely remains a fair and equitable plan. It seldom serves to encourage superior professional ability or to promote improvement in professional attainment.

It would therefore be our opinion that the resolution adopted by the House of Delegates in 1943 (June 8, 1943, published in *THE JOURNAL*, June 26, 1943, p. 619) expresses a proper attitude which ought to be maintained.

The redrafted resolution concerning the Horace Wells centenary year was read and ordered placed in the minutes, as follows:

WHEREAS, It has been well established that Horace Wells of Hartford, Conn., was one of the first to suggest a practical method of rendering the human body insensible during surgical operations;

WHEREAS, He was the first to show that nitrous oxide could be used as an anesthetic agent and himself used nitrous oxide in many operations;

WHEREAS, He at once made known his discovery to members of the medical and dental profession in Hartford and elsewhere, showing thereby a commendable desire to make known to others the knowledge of his great discovery; therefore he it

Resolved, That, since 1944 marks the centenary of the discovery by Horace Wells, this society believes this is an appropriate time to honor his memory.

The resolution was accepted by unanimous vote.

Dr. Paul M. Wood, New York, read the chairman's address, entitled "Some Aims of an Anesthesiologist."

Dr. Robert A. Hingson, P. A. Surgeon, U. S. P. H. S., read a paper entitled "Continuous Caudal Analgesia: A Technique in Therapeutics, Surgery and Obstetrics." Discussed by Drs. John G. P. Cleland, Oregon City, Ore., and H. Close Hesselstine, Chicago.

Dr. John Adriana, New Orleans, read a paper on "The Effect of Moisture on the Absorption Efficiency of Soda Lime." Discussed by Dr. James H. Bennett, Cincinnati, and Capt. Ralph Sappenfield, M. C., A. U. S.

Dr. R. Charles Adams, Rochester, Minn., read a paper entitled "Intravenous Anesthesia." Discussed by Drs. Alice McNeal, Chicago; Robert A. Hingson, U. S. P. H. S.; S. A. Swenson, Rushville, Neb.; H. A. Cunningham, Milwaukee; K. C. McCarthy, Louisville, Ky.; Herman Lenowitz, Maywood, Ill., and Stuart C. Cullen, Iowa City.

Dr. E. A. Rovenstine, New York, read a paper on "Therapeutic and Diagnostic Nerve Blocking." Discussed by Drs. H. O. Brown, Chicago, and Major Harold Bishop, Washington, D. C.

FRIDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Nervous and Mental Diseases. The proceedings are reported in the minutes of that section.

SECTION ON MISCELLANEOUS TOPICS

Sessions for the General Practitioner

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:10 by the chairman, Dr. J. Craig Bowman, Upper Sandusky, Ohio.

Dr. J. Craig Bowman, Upper Sandusky, Ohio, read the chairman's address, entitled "The Role of the General Practitioner."

Dr. Sidney A. Portis, Chicago, read a paper on "The Medical Treatment of Psychosomatic Disturbances, with Special Reference to the Gastrointestinal Tract and Fatigue." Discussed by Col. Leonard G. Rowntree, M. C., A. U. S., and Drs. Hobart A. Reimann, Philadelphia, and Dr. Sidney A. Portis, Chicago.

Dr. M. A. Blankenhorn, Cincinnati, read a paper on "The Newer Sulfonamides." Discussed by Drs. Lawrence D. Thompson, St. Louis; S. L. Bernstein, Cleveland; David Lehr, New York, and M. A. Blankenhorn, Cincinnati.

Dr. Wallace E. Herrell, Rochester, Minn., read a paper on "Penicillin Therapy: Its Use and Limitation." Discussed by Drs. Walter S. Priest, Chicago; K. R. Brown, Des Moines, Iowa; W. M. Johnson, Winston-Salem, N. C., and Dr. Wallace E. Herrell, Rochester, Minn.

Dr. John A. Toomey, Cleveland, read a paper on "Chief Complaint: Stiff Neck." Discussed by Drs. Archibald L. Hoyne, Chicago; Gilbert J. Levy, Memphis, Tenn., and John A. Toomey, Cleveland.

Dr. Royal M. Montgomery, New York, read a paper on "Cutaneous Manifestations of the Fungi Causing Dermatophytosis and Onychomycosis and Their Treatment." Discussed by Drs. John H. Lamb, Oklahoma City, Arthur C. Curtis, Ann Arbor, Mich., and Royal M. Montgomery, New York.

THURSDAY, JUNE 15—MORNING

Dr. William Earl Clark, Washington, D. C., read a paper on "Gastrointestinal Conditions Simulating or Aggravating Cardiovascular Diseases." Discussed by Drs. Sara M. Jordan, Boston, and William Earl Clark, Washington, D. C.

Lieut. Col. William J. Carrington, M. C., A. U. S., read a paper on "Diagnosis of Acute Surgical Diseases of the Female Pelvis and Lower Abdomen."

Lieut. Col. Thomas T. Mackie, M. C., A. U. S., read a paper on "The Dysenteries: Acute and Chronic." Discussed by Dr. George T. Harrell Jr., Winston-Salem, N. C.; Capt. William C. Bernstein, M. C., A. U. S., and Lieut. Col. Thomas T. Mackie, M. C., A. U. S.

Dr. August A. Werner, St. Louis, read a paper on "The Male Climacteric." Discussed by Drs. Charles W. Dunn, Philadelphia; Benjamin F. Sieve, Boston, and August A. Werner, St. Louis.

Dr. E. J. Teeter, Indianapolis, read a paper on "Anemia Therapy: Review of Various Liver and Stomach Fractions and Iron Salts." Discussed by Drs. Francis D. Murphy, Milwaukee; Raphael Isaacs, Chicago, and E. J. Teeter, Indianapolis.

OFFICIAL NOTES

COMMITTEE ON POSTWAR MEDICAL SERVICE

Meeting Held in the Palmer House, Chicago,
June 14, 1944

Members and guests present

Dr Roger I Lee	Lieut Col Richard L Weislag
Dr H H Shoulders	Dr E E Irons
Dr Frederick A Collier	Dr E R Loveland
Dr Willard C Rappleye	Brig Gen Fred W Rankin
Dr Graham G Davis	Major Gen B T Kirk
Dr Victor Johnson	Major Gen George Lull
Lieut Col Gerard R Gessner	C Willard Camahner, DDS
Lieut Col George Powell	Dr Arthur W Allen
Lieut Col Harold C Lueth	Dr Irvin Abell
Dr Francis G Bluke	Dr Harvey Stone
Capt W Baker	Dr Walter L Biering
Dr James E Paulin	Dr Olin West
Miss Mary E Switzer	Vice Admiral Ross T McIntire
Dr Morris Fishbein	Capt William Eaton
Rev Alphonse Schwitalla	

In the absence of the secretary of the committee, the chairman requested Dr H H Shoulders to serve as temporary secretary.

The chairman announced the presence of new members of the committee. Mr Graham Davis, representing the American Hospital Association, and Rev Alphonse Schwitalla, SJ, representing the Catholic Hospital Association.

REPORT OF ACTION TAKEN BY THE HOUSE OF DELEGATES

The chairman at this point read a statement of the action taken by the House of Delegates of the American Medical Association on the report to the House by Dr Roger I Lee, chairman of the committee. The action was entirely favorable to the activities of the committee and to its continuance in service.

LEGISLATION AFFECTING VETERANS

The next question raised was the status of current legislation affecting the educational privileges and financial aids of veterans of this war. Particular reference was made to the status of the bill referred to as the G I bill.

It was recommended that Mr J W Holloway of the Bureau of Legal Medicine and Legislation of the American Medical Association make an analysis of all current national legislation concerned with educational privileges and financial aid to veterans of this war and submit his analysis to the members of this committee.

ANALYSIS OF PILOT QUESTIONNAIRE

An analysis of 927 returned pilot questionnaires was presented by Lieutenant Colonel Lueth. This report will appear in an early issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. The large number of returned questionnaires (31 per cent) indicates a genuine interest among medical officers in active postwar planning. Medical officers particularly young medical officers, are greatly interested in the creation of immediate postwar educational training programs.

PUBLICITY OF COMMITTEE ACTIVITIES

A motion was made by Miss Mary E Switzer and seconded by Dr Paulin that publicity be given to this analysis better to acquaint medical officers in the field, as well as practitioners at home, with the detailed groundwork that has been done incident to the formulation of sound postwar policies. It was further pointed out that an explanation of the purpose of the questionnaire to the doctors would facilitate a better return of the final questionnaire soon to be sent to each medical officer. The motion was put to a vote and carried.

REVISED QUESTIONNAIRE

As a result of the returned pilot questionnaires, certain revisions appeared desirable. At the last meeting of the Committee on Postwar Medical Service a committee composed of Dr Abell, Dr West, Dr Irons and Lieutenant Colonel Lueth was empowered to make such revisions in the final questionnaire as appear necessary. The revised questionnaire was presented and the committee was informed that the questionnaires are printed and are shortly to be distributed to the Army, Navy and Public Health Service for early mailing to medical officers.

PLANS AND FACILITIES FOR POSTGRADUATE TRAINING

Dr Victor Johnson, Secretary of the Council on Medical Education and Hospitals of the American Medical Association reported progress on the study of available facilities for postgraduate training in the form of residencies, internships, short courses, and so on, that will be available for medical men immediately after the cessation of hostilities. In particular it was recommended that the Council on Medical Education and Hospitals be given authority to explore the possibilities of the developments of a six to eight weeks course for a small number of medical officers who are about to be discharged from the armed services. The plan was discussed by Dr Abell, Dr Stone, Dr Rappleye, Father Schustalla and Lieutenant Colonel Lueth. General Kirk and Vice Admiral McIntire were requested to express an opinion on the feasibility of such plans. While they were in accord with the formation of short refresher courses, they pointed out certain limitations and indicated that such plans could not be put into operation in the immediate future because of the enlarging demands of both services for medical personnel, which needs have not been completely satisfied at present.

After full and free discussion, Dr Abell moved that the Council on Medical Education and Hospitals be requested to work out a program for such a course in postgraduate training as an experiment. This was put to a vote and carried. Vice Admiral McIntire agreed to supply the Council with a list of naval officers now in various medical institutions for training.

BUREAU OF INFORMATION

Dr Irons, chairman of the subcommittee, reported that the Board of Trustees and the House of Delegates of the American Medical Association have taken action to create a Bureau of Information to be established at 535 North Dearborn Street, Chicago 10, Illinois and to make its facilities available to all who may be interested. This bureau was created primarily to serve as an information service to discharged veterans and to institutions and localities for their mutual benefit in facilitating the placement of personnel. The new agency is in no sense to serve as an employment agency, and to this end the Information Bureau will be in operation only during the period of demobilization.

DISPOSITION OF EXCESS MEDICAL SUPPLIES AND EQUIPMENT

The next question concerned the matter of disposition of government owned medical supplies and equipment currently on hand in warehouses as excess material. In particular, reference was made to equipment and supplies no longer needed by the Office of Civilian Defense. It was reported that the large stores of supplies and equipment might deteriorate in storage if not used, consequently they might be put to practical use if satisfactory plans for disposition could be arranged. It was pointed out that certain governmental agencies are vitally concerned with the program and would welcome the advice and assistance of the committee.

It was moved by Dr H H Shoulders and seconded by Dr Arthur W Allen that Chairman Lee be authorized to appoint a subcommittee to explore this question and report back to the committee at its next meeting. This motion was put to a vote and carried.

During the discussion of the uses of excess medical equipment and supplies it was suggested that means of ascertaining the effects of deterioration and contamination should be carefully considered by the subcommittee.

Capt William Eaton, U S N, recommended that a medical officer representative of the governmental services be made ex officio a member of the Committee on Supplies and Equipment.

In view of the complexity and gravity of the problems of distribution of excess medical supplies, the chairman asked that he be given sufficient time during which to consider the appointment of members of the committee.

FACILITATING MEDICAL LICENSURE

Dr Walter Biering offered the facilities of the Federal and State Boards of Medical Examiners in working out problems concerned with the licensure of returning veterans.

There being no further business, the Committee adjourned to meet in New York City at a time to be fixed by the chair.

The chairman appointed W W Palmer, E F Irons, Dr Schwitalla, Morris Fishbein and M E Switzer as a committee on Excess Medical and Hospital Supplies.

WASHINGTON LETTER

(From a Special Correspondent)

June 26, 1944.

Maternity Care

Doctors in the District of Columbia, now paid a flat \$50 fee for maternity care of servicemen's wives, will get additional fees effective July 1 from the government when necessary treatment of intercurrent conditions requires repeated professional calls at home or hospital, officials of the maternity and child welfare section of the District of Columbia Health Department disclose.

This liberalization of maternity care payments is expected to eliminate one of several dissatisfactions of doctors and patients which has limited effectiveness of the plan intended by Congress to aid the wives of lowest paid soldiers and sailors in the fourth, fifth, sixth and seventh pay grades.

Altogether 254 Washington doctors are accepting patients under the plan; so far as service wife-and-child patients are concerned, the arrangement is much more liberal than it sounds.

Some Washington obstetricians limit the number they will accept to 2 a month or 3 a month; one doctor has 71 service maternity patients under the plan, another 30, and the majority under 10 each.

No limit is fixed on hospital care; the mother stays as long as she needs hospitalization, and the health department pays her bill on the basis of hospital contracts negotiated with cooperating institutions—Columbia, Freedmen's, Gallinger, Garfield, Georgetown, George Washington, National Homeopathic, Providence and Sibley.

Marriage Regulations

Another effort has been made to bring District of Columbia marriage regulations into line with the thirty states which require compulsory medical examination of all applicants for marriage licenses. The bill, presented to the House by Chairman Jennings Randolph (Democrat, West Virginia) of the House Committee on the District of Columbia would require examination for syphilis, gonorrhea and tuberculosis. An iden-

tical measure was introduced in 1941 at the request of the District commissioners, but no action was taken on it. Neighboring Maryland also lacks premarital regulations, but Virginia enforces them.

The bill stipulates that applicants for marriage licenses must submit a physician's certificate stating that serologic or other recognized laboratory procedure had been undertaken within thirty days of making the application. Tests would be made without charge by the district health department. Penalty of \$500 fine or up to six months' imprisonment or both is provided for violations.

District health officials are in favor of legislation to require antepartum examination to protect babies against syphilis, but this is not included in the bill. Neither Maryland nor Virginia has such a law.

Shortage of Nurses

Washington hospitals are finding a partial answer to the acute shortage of nurses in the use of hospital men volunteers, joint project of the Office of Civilian Defense and the American Hospital Association. Doctors Hospital has signed 45 men for volunteer nurse duty, among them civil service workers, businessmen, accountants, lawyers and clerks. Welcomed by Dr. Edgar Bocock, Doctors Hospital administrator, they began work on four hour shifts, assigned to floor duty as orderlies. Dr. Bocock outlined a plan for appealing to other volunteers in kitchen, housekeeping and clerical work.

Hospital men volunteers are also being enrolled at Emergency and Garfield Hospitals, with other hospitals here to put the program into effect later.

After collapse of a plan to get services of conscientious objectors through Selective Service, Dr. George C. Ruhland, District of Columbia health officer, tried to obtain paroled jail prisoners to meet personnel needs at Glenn Dale Sanatorium and Gallinger Municipal Hospital. He has written to James V. Bennett, director of the Federal Bureau of Prisons to learn if prisoners could be detailed or paroled to the District institutions. Housing and food would be furnished workers, and the city might offer some pay if permitted.

MEDICAL ECONOMIC ABSTRACTS

NEW HAMPSHIRE PREPAYMENT PLAN

The New Hampshire Physician Service has begun operation in cooperation with the New Hampshire-Vermont Hospitalization Service. Joint contracts are issued at a monthly cost to the subscriber of \$2.25 for an individual and \$5.25 for the family, covering hospitalization, surgical service and medical service. Of the payments from the individual 75 cents is assigned to each of the three types of service, and the family contributions are also distributed giving \$1.75 for each class of service.

The Blue Cross New Hampshire-Vermont Hospitalization Service administers the hospital section, while the Surgical and Medical Indemnity Services are in a separate division under the direction of the New Hampshire Medical Service. The governing power is vested in the "voting members," of which at least one half must be members of the New Hampshire Medical Society. The "voting members" choose the board of directors, "at least a majority of whom shall be approved by the house of delegates of the New Hampshire Medical Society, and one of whom shall be the president of the New Hampshire Hospitalization Service." The board of directors is to choose from its own membership a "professional committee," which "shall have supervision over the medical aspects of all matters relating to (a) the standards of medical care provided subscribers, (b) the qualifications of participating physicians, (c) the admission, suspension or disciplining of participating physicians, (d) the amount of credits allowed for service not specifically specified in the schedule of benefits and (e) any matters in dispute between the subscriber and the participating physician, or between the corporation and the participating physician."

The payments to physicians for services are on the indemnity plan and do not prevent additional charges. The first two visits are deductible, and paid for by the subscriber, and only twenty-five visits will be paid for during a single year. Contracts for medical services are granted only to those having surgical contracts.

REPORT OF THE NEW JERSEY PLAN

The Medical-Surgical Plan of New Jersey submitted a supplementary report to the House of Delegates of the Medical Society of New Jersey which gives the results of twenty-one months of operation ended March 31, 1944. From this report the following is taken:

As of March 31 there were 20,460 persons enrolled in the plan.

The plan has received from its subscribers \$120,884.69 and has paid \$71,226.75, or 58.9 per cent, of this income to physicians for medical and surgical services rendered its subscribers and dependents.

From its earned income it has paid all administrative costs, all eligible claims in accordance with its predetermined schedule of benefits and placed \$19,850.33, or 16.4 per cent, of its earned income in reserve. In addition it retains intact the \$5,000 capital fund donated by the Medical Society of New Jersey.

The state legislature passed a bill on April 13, 1944 permitting an expansion of the plan under certain conditions to include patients not hospitalized.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Major Greene Returns as Director of Laboratories.—Major Robert A. Greene, U. S. Army Chemical Warfare Service, who received an honorable discharge May 8, has rejoined the state department of health as director of laboratories, a position he had held for six years prior to his military leave. Mildred T. Wooley, D.P.H., who has been director of the laboratory since August 1941, will return to her home in California, according to *Arizona Public Health News*. Dr. Greene received his degree of doctor of philosophy at the University of Arizona, Tucson, in 1933.

COLORADO

Medical Journal Dedicated to Donald Cummings.—The *Rocky Mountain Medical Journal* for June was designated the Donald E. Cummings Memorial Number in honor of the man who on Dec. 15, 1942 died in an airplane crash in Utah while on his way from Denver to Nevada to give advice and protection to the employees of an essential industry. Mr. Cummings was associate professor in the department of medicine, University of Colorado School of Medicine, Denver, and was made director of a division of industrial hygiene created in 1937 at the medical school. While teaching chemical engineering at the Massachusetts Institute of Technology, Cambridge, Mr. Cummings developed pulmonary tuberculosis. He went to Saranac Lake, N. Y., for treatment and entered the Saranac Laboratory about 1926 for the study of tuberculosis as a research chemist, later being appointed assistant director. In 1932 he organized a field division of the Saranac Laboratory and became its director. During this entire period until the time of his death Mr. Cummings was active in forwarding the knowledge on industrial diseases. He assisted in setting up a laboratory of industrial toxicology at the University of Colorado School of Medicine and rehabilitation clinic in the Colorado General Hospital. He was an organizer and president of the American Industrial Hygiene Association.

FLORIDA

Graduate Short Course.—The annual graduate short course sponsored by the Florida Medical Association was held in Jacksonville, June 19-24. Speakers included:

Dr. Eugene A. Stead Jr., Atlanta, Ga., medicine.
Dr. Samuel F. Ravenel, Greensboro, N. C., pediatrics.
Dr. Oren Moore, Charlotte, N. C., obstetrics.
Dr. Robert L. Sanders, Memphis, Tenn., surgery.
Dr. Clayton T. Beecham, Philadelphia, gynecology.

State Medical Election.—Dr. Shaler Richardson, Jacksonville, was chosen president-elect of the Florida Medical Association at its recent annual meeting, and Dr. John R. Boling, Tampa, was inducted into the presidency. Other officers are Drs. Whitman C. McConnell, St. Petersburg, Horace A. Day, Orlando, and Robert D. Ferguson, Ocala, vice presidents; Robert B. McIver, Jacksonville, is secretary-treasurer, and Stewart G. Thompson, D.P.H., Jacksonville, managing director. Appointment of Dr. Homer L. Pearson of Miami as editor of the *Journal of the Florida Medical Association* was reported in *THE JOURNAL*, June 3, page 367.

GEORGIA

Dr. Kelly Returns as Dean.—On July 1 Dr. G. Lombard Kelly, who has been Secretary of the Council on Medical Service and Public Relations of the American Medical Association under a six months leave granted by the University of Georgia School of Medicine, Augusta, returned to the medical school as dean and professor of anatomy.

ILLINOIS

Physician Outlives Life Expectancy.—Dr. Jolm H. Burlingame, Evanston, formerly of Cherokee, Iowa, who observed his ninety-sixth birthday on March 8, was presented with a check for \$1,273 by the Union Central Life Insurance Company, June 22. In presenting the check, officials said that he was "one man in a hundred thousand," having outlived the

expectancy of the company's policy. Dr. Burlingame, who graduated at Rush Medical College in 1878, retired in 1927. He practiced in Cherokee for forty-seven years and served ten years as mayor.

CHICAGO

Personal.—George Peck, formerly assistant superintendent of Michael Reese Hospital, was recently appointed superintendent of the Illinois Eye and Ear Infirmary, succeeding Dr. John B. Cipriani.

Special Society Elections.—Dr. Charles M. Drucek Jr. was installed as president of the Chicago Society of Industrial Medicine and Surgery, Dr. J. Daniel Willems as vice president and Dr. Frank P. Hammond as secretary-treasurer.—Dr. Lester M. Wieder is president of the Chicago Dermatological Society, Dr. Frederick R. Schmidt vice president and Dr. Marcus R. Caro secretary-treasurer.

INDIANA

Personal.—Dr. Frank E. Wiedenmann, Terre Haute, recently observed his fiftieth anniversary in the practice of medicine.—Dr. John William Herr, formerly of Millhousen, has been named health commissioner of Posey County to fill the unexpired term of Dr. William E. Jenkinson, resigned.

Physician Goes to Nigeria as Medical Missionary.—Dr. and Mrs. Howard A. Bosler, New Paris, recently sailed for Nigeria, where they have taken work as medical missionaries. According to the *Journal of the Indiana State Medical Association* Dr. Bosler will be in charge of an area covering 150 miles, which includes two general hospitals, a number of first aid stations and a large leper colony. The physician and his wife expect to return in four years. This is said to be the third trip to Africa for Dr. and Mrs. Bosler.

IOWA

Report on Use of Serum or Plasma.—The division of preventable diseases of the Iowa State Department of Health, under the direction of Dr. Carl F. Jordan, Des Moines, has issued a report concerning the use of human serum and plasma during a limited period through which its Serum-Plasma Center has functioned. During 1943 and the first four months of 1944 case reports totaled 214, of which 165 contained needed information. In the series of 165, accidental injuries, including burns, accounted for 39 cases; 34 were due to complications of pregnancy and 92 to surgical conditions. In 113 instances (68.5 per cent) the result of use of serum or plasma was stated as "good." Fatalities in the group of 165 numbered 28, a case fatality of 17 per cent.

KANSAS

Changes in Health Officers.—Dr. Edwin M. Ireland has been appointed health officer of Pratt County to succeed Dr. Ernest J. Beckner, who was transferred to Butler County. P. A. Surg. Thurman R. Laughbaum, U. S. Public Health Service, has been appointed health officer of Geary County to succeed Dr. Norman A. Burkett, Junction City, who has resigned to enter the Army.

MASSACHUSETTS

State Medical Election.—Dr. Reginald Fitz, Boston, was chosen president-elect of the Massachusetts Medical Society at its meeting in Boston, May 22-24. Dr. Elmer S. Bagnall, Groveland, was inducted into the presidency. Other officers include Drs. Sumner H. Remick, Waltham, vice president, Michael A. Tighe, Boston, secretary, and Eliot Hubbard Jr., Cambridge, treasurer.

Licenses Revoked.—The license of Dr. Harry J. Weintraub, Malden, was revoked by the state board of registration in medicine, May 17, because of gross misconduct in the practice of his profession. At the same meeting the board, for a similar reason, revoked the licenses of Drs. Louis L. Hoff, Holyoke, Ray D. Hester, West Warren, William D. Ducey, Brockton, and Ralph K. Coleman, Lowell.

Foundation for Experimental Biology Increases Staff.—Three new research members of the Worcester Foundation for Experimental Biology include Erwin Haas, Ph.D., of the University of Chicago; Robert P. Jacobsen, Ph.D., of the U. S. Public Health Service, and Oscar Hechter, M.S., of the University of Southern California. According to *Science* Dr. Haas's work is primarily in the field of respiratory enzymes. Dr. Jacobsen is a steroid chemist, and Dr. Hechter's contributions have been primarily in endocrinology (*THE JOURNAL*, May 13, p. 110).

MICHIGAN

Fellowships in Pathology.—Mount Carmel Mercy Hospital, Detroit, has made available \$2,000 annually to the city board of education to be used to establish fellowships for young physicians specializing in pathology. The fellowships are available to Wayne University students, and it was proposed that students holding these fellowships register at the Wayne University Graduate School and qualify for the master's degree.

Memorial to Physician.—Citizens of Saugatuck have raised a fund to finance the erection of a memorial to the late Dr Robert J Walker. The memorial will be erected in the southeast section of Butler Park, in the vicinity of which Dr Walker spent a great part of his life. It will consist of a drinking fountain bordered by five concrete slabs reaching out to the sides forming a half circle, representing the five decades of service of Dr Walker to the community.

Licenses Revoked.—The licenses to practice medicine of Drs Martin B Robinson and Fred W Thomas, both of Detroit, have been revoked, newspapers reported June 16. According to the *Detroit News*, Dr Robinson was convicted in Wayne Circuit Court of conspiracy to obstruct justice and was sentenced to three to five years in the state prison. His appeal to the Michigan Supreme Court was denied. The report stated that the physician's arrest and conviction resulted from the grand jury investigation of graft in Wayne County. Dr Robinson recently went into federal court on a writ of habeas corpus, claiming that his constitutional rights had been violated and that he had been convicted illegally. This phase of the case is pending, and he is held temporarily in the county jail. Dr Thomas was convicted in federal court of violating the Espionage Act as an alleged member of a Nazi spy ring in Detroit and was sentenced to serve sixteen years in federal prison. An appeal from the conviction has been filed (*THE JOURNAL*, April 1, p 1000).

NEW JERSEY

Rutgers Research Council.—A research council has been established at Rutgers University, New Brunswick, to promote research in all departments of the university. William H Cole, Ph.D, since 1928 professor of physiology and biochemistry at Rutgers, has been appointed director of the council and will serve in a staff relationship to deans, heads of departments and members of the faculty concerning the research programs. He will represent the university in developing reciprocal arrangements with governmental, industrial and business and professional institutions outside the university. According to *Science* a special research fund has been placed at the disposal of the council and applications for grants for next year are now being considered.

Philip Levine Joins Ortho Research Foundation.—Dr Philip Levine, since 1935 bacteriologist and serologist of Newark Beth Israel Hospital, Newark has been appointed director of the biologic division of the Ortho Research Foundation, Linden. Dr Levine graduated at Cornell University Medical College, New York, in 1923. For a time he served as assistant at the Rockefeller Institute and for a number of years on the faculty of the University of Wisconsin. The Ortho Research Foundation was established January 17 by Ortho Products, Inc, Linden. For the present it will be located with the new research division of the company. The foundation will consider requests from academic centers for grants twice annually, April 1 and October 1. The requests should be accompanied with an outline of the study. The organization of the foundation was one of several steps taken by Ortho Products, Inc, to broaden its program in the various phases of human fertility. Among its studies will be vaginal infections and infestations, toxemia of pregnancy, multitudinous problems of menstruation, physiologic imbalances in pregnancy and psychosomatic problems in gynecology. Dr Clair E Folson, New York, is director of research for the foundation.

NEW YORK

Graduate Lectures.—Dr Nathan P Sears, Syracuse, will discuss "Gynecology in General Practice" before the Ontario County Medical Society in Geneva, July 11. Drs Francis R Irving and Charles A Lippincott, both of Syracuse, discussed "Caudal Anesthesia in Obstetrics." The lectures are a part of a graduate series in obstetrics and gynecology sponsored by the state medical society and the state department of health.

Sale of Vitamin Tablets Curbed.—Attorney General Nathaniel L Goldstein ruled on June 23 that vitamins, when listed in the official United States Pharmacopoeia or National Formulary, were drugs and could be sold retail only by regis-

tered pharmacists, drug stores and registered stores. According to the *New York Times*, the action may lead to a court test or a drive at the next session of the legislature for an amendment to the law to permit general retail sale because of the thousands of stores, including department stores which have been selling concentrated vitamins. Mr. Goldstein gave the ruling in response to a letter, June 9, in which Leslie C Jayne, secretary of the state board of pharmacy, asked

whether vitamin products in concentrated form that is pills, tablets, capsules and drops, come under the classification of drugs as provided in article 51, Education (pharmacy) Law.

Is their sale restricted to places licensed by the New York State Board of Pharmacy?

Dr Jayne, in his letter, informed the attorney general that vitamins are articles recognized in the official United States Pharmacopoeia, there appearing in the Pharmacopoeia monographs setting forth the standards for vitamins A, B₁, B₂ or G, C and D and preparations containing these vitamins. Mr Goldstein said that his opinion was concerned only with vitamins in concentrated form, as distinguished from their natural state as found in vegetables, meat and other articles of normal diet. In his reply Mr Goldstein stated that vitamins are not proprietary medicine.

A later report in the *Times* indicated that grocers throughout the state were protesting the ruling because of the fact that it would give drug stores a "virtual monopoly" in New York on a business that amounts throughout the nation to \$250,000,000 a year.

New York City

New Boric Acid Labeling Effective September 15.—On June 10 the New York City board of health announced that the enforcement of the new labeling requirements for boric acid had been postponed for a period of three months "to avoid confusion," it is reported. The enforcement date will be September 15 instead of June 15 (*THE JOURNAL*, June 17, p 505).

Camp Nyda for the Diabetic Opens.—On July 3 Camp Nyda, a camp for diabetic boys and girls at Walkill, was opened for its ninth consecutive season under the auspices of the New York Diabetes Association. Dr Frederick W. Williams, a director of the association, is in charge of the medical department of the camp. Any one wishing to send funds to assist in the project may address donations to the New York Diabetes Association, 2 East 103d Street. According to the *New York Times*, at least \$7,365 is needed to send 100 children to the camp for a two weeks vacation. It costs about \$30 a week a child to finance special medical care, rigid diet requirements and the other special attentions. Camp Nyda is the only free diabetic camp for children in the New York area.

Biologic and Pathologic Research Center Planned.—Postwar plans of the New York Zoological Society include the construction of a \$200,000 biologic and pathologic research center at or near the Bronx Zoo, it is reported. Forty-three fellows of the society, attending a meeting at which the announcement was made, gave wholehearted support to the project. The new facilities would include studies of animal behavior, infection and cancer. Only animals that become sick will be used for experimental purposes, it was stated. The center will be open twenty-four hours a day and will be available to students in medical centers and universities. Tentative plans call for a two story building consisting of laboratories for research in chemistry, biology, bacteriology, parasitology and physiology. According to an announcement of Fairfield Osborn, president of the New York Zoological Society, the plan is unique and it is believed to be the first time that any zoo has tried to collaborate so closely with science. In commenting on the plan, Dr Francisco Duran-Reynals, associate professor of bacteriology at Yale University School of Medicine, New Haven, said "The program outlined could best be carried out by creating an Institute for the Comparative Study of Infection, or the Institute of Comparative Pathology, as a branch of the New York Zoological Society. The institute would take advantage of the animal resources of the Bronx Park and the Aquarium, and of the zoological and technical skills on which these resources are dependent."

Dr. Moorhead Retires as Medical Director of Transit System.—On August 1, after a month's vacation, Dr John J Moorhead will retire as medical director of the New York City Transit System. He was medical director of the Interborough Rapid Transit system for thirty-six years and with the unification became director four years ago of the city's transit system according to the *New York Times*. Dr Moorhead will be 70 years old July 15. On Dec 7, 1914 Dr

cal Women's Association chosen at its annual meeting in Chicago, June 10-11, are Drs. Kate Savage Zerfoss, Nashville, Tenn., president-elect; Alice Stone Woolley, Poughkeepsie, N. Y., president; Carroll C. L. Birch, Chicago, Margaret Virginia Beyer, Sykesville, Md., and Mary B. Campbell, Detroit, vice presidents; Isabel M. Scharnagel, New York, secretary, and Mary Riggs Noble, Bowmansdale, Pa., treasurer.—Dr. Edward Sterling Nichol, Miami, Fla., was chosen president of the American Therapeutic Society at its meeting in Chicago, June 10, and Drs. Thomas J. Coogan, Chicago, and Charles L. Hartsock, Cleveland, were named vice presidents. Dr. Oscar B. Hunter, Washington, D. C., was reelected secretary.

LATIN AMERICA

Health Activities in Latin America.—Report of Inter-American Health Service in Paraguay.—A report has been published covering the first two years of operation of the Inter-American Cooperative Health Service in Paraguay. Appearing in the *Newsletter of the Health and Sanitation Division of the Office of the Coordinator of Inter-American Affairs*, the report covers the two year period from 1942 to 1944. One of the first undertakings of the cooperative health service in Paraguay was the construction of a large building in Asunción to provide office space for the ministry of health, the director of the department of public welfare and the director of the department of hygiene, as well as space for a number of the divisions of the department of hygiene and the principal health center for Asunción. The health center section of the building will provide clinics for general medicine, tuberculosis, maternal and child hygiene, syphilis and skin, dentistry and eye, ear, nose and throat. A large public health laboratory will also be housed in the building. This laboratory will perform all bacteriologic and serologic examinations and analysis for the various divisions of the ministry of health as well as for the new health center. The building will also house the pharmacy of the ministry of health. The building contract for construction was let during November 1942. By May 1944 the entire project was over three-fourths finished. It is estimated that the building will be ready for operation during the latter part of 1944. The widespread program includes the establishment of five health centers in five localities, four of which either share a building with a hospital or are connected with the hospital by covered passageways. In each of these four instances the laboratory, pharmacy and x-ray section are built in the health center, designed to serve both institutions. This combined use of personnel and facilities was particularly practical in Paraguay, not only in terms of good public health procedure but because of the scarcity of equipment and the limited number of available medical personnel. The centers are in the Barrio Obrero section, Asunción; Encarnación and Concepción. At the time of the report, construction was under way for a center at Villarrica and a second one in Asunción. In July 1942 Cooperative Health Service made plans to remodel extensively the Hospital Nacional de Clínicas, the principal hospital in Paraguay operated under the supervision of the Academy of Medicine of the National University with funds provided by the ministry of public instruction and justice to serve as a general hospital and teaching institution of the academy of medicine. There are about 600 beds, and the clinics of the hospital serve an average of 500 ambulatory patients daily. The improvements included the installation of a safe water supply and sewerage system, rebuilding and equipping of the hospital kitchen, conversion of the present administration building into central hospital laboratory, screening, painting and renovating the entire hospital building and generally improving and increasing nursing instruction facilities in both the surgical and the medical sections of the hospital. The entire project was expected to be completed sometime in July. Additional construction for the care of the sick included a 100 bed tuberculosis sanatorium at Asunción, with provisions for future expansion into a 300 bed unit. At the present time facilities for treating tuberculosis are limited to 60 or 70 beds made available in the National Hospital de Clínicas. In 1941 the recorded death rate from tuberculosis in Asunción was 196 per hundred thousand persons. As a part of the plan the national government donated a large tract of land valued at \$21,000 on the edge of the city as the site for the building, which by May 1944 was half-way completed. Accommodations call for 40 beds each for men and women and 20 beds for children. The Barrio Obrero Hospital in Asunción, started by a group of students of the Medical University Extension Association in 1936, was remodeled under the auspices of the cooperative health service and an addition erected to provide a combination 50 bed hospital and health center, with x-ray

and laboratory sections to serve both units. The addition was completed during June 1943, and 18 hospital beds, together with all health center activities, were moved into the new section in order that the old part of the hospital might be changed into a health center. The hospital section contains 12 obstetric beds, a nursery with 12 bassinets, 17 surgical beds, 10 medical beds, 8 children's beds and 3 for isolation.

At the request of the minister of health during September 1942 and again during January 1944, Malcolm H. Soule, Sc.D., special consultant to the Coordinator of Inter-American Affairs and member of the medical advisory board of the Leonard Wood Memorial, visited the leper colony in Paraguay to study the social and medical needs. This 4,000 acre colony is located over 7 miles by an ox cart road from Sapucay. In September 1942 the number of patients totaled 386 in all stages of the disease. Dr. Soule recommended the construction of a 100 bed hospital at Sapucay, believing that because of the present inaccessibility of the colony a number of patients do not report the disease. An alternative was the construction of an adequate road to the existing colony. The latter project is soon to be started. In the meantime a brick plant has been built at the colony with the aid of ambulatory patients to manufacture bricks and tile for the proposed hospital. Dr. Manuel Gimenez Uriarte, who recently completed fourteen months of study of the disease in Rio de Janeiro on a scholarship provided by the Brazilian government, is director of the leper colony. As a result of the recommendation of Dr. Soule that children born to leprosy parents be separated from the mother at once, a preventorium has been constructed, including five buildings with a 24 bed dormitory for boys, a similar one for girls, a 16 bed nursery building, an administration building, also housing the main dining room, and a small laundry building. During the first month of operation after it was completed in January 1944, 26 children from the ages of 9 months to 13 years were removed from the colony to the preventorium, of which Dr. Ovidio Miquel is medical director. Supporting Dr. Miquel and his staff is the Asociación de Ayuda a los Lazeros y Defensa contra la Lepra, which has been instrumental in obtaining funds and clothing for the children in the preventorium. After his visit to the preventorium in January, Dr. Soule commented: The preventorium including the crèche, or nursery, is at this moment the envy of every individual associated with leprosy work. I know of no institution to equal it.

The construction of a laboratory in Asunción for the bacteriologic and chemical analyses of water and milk, and sewage, is another accomplishment of the service. The laboratory was set up in a section of the building recently completed by the ministry of health at the Instituto de Higiene with the Inter-American Cooperative Health Service furnishing the equipment and the maintenance. Dr. Domingo Sanjurjo is director and bacteriologist and Dr. Francisco Ocaris assistant. Since its establishment the laboratory has completed a systematic examination of all public and private water supplies.

The report discusses the training of professional and technical personnel, the provision of fellowship, the medical training for nurses, and scholarships for sanitary inspectors. Public health education activities are launched with a series of radio broadcasts by public health and private physicians. In December 1942 a special health week was observed by radio. From August through December 1942 thirty-two talks were given in which venereal disease, tuberculosis and cancer were particularly emphasized. During 1943 three senior medical students in the Faculty of Medical Sciences were employed as lecturers. Talks were given in schools, factories, health centers and other gathering places. In two months thirty-nine conferences were attended by more than 3,500 persons.

Mr. Charles G. Bennett was sent as a representative of the U. S. Bureau of Census to assist in the organization of the division of vital statistics in the ministry of health and in the training of local personnel. Medical journals and textbooks were supplied to the leading medical schools and hospitals in Paraguay. The report also includes mention of a special malaria survey in the Hernandarias region of the upper Parana River and included the study of a tract of land which the Paraguayan government is considering for the location of a resettlement colony.

CORRECTION

Chemotherapy of Burns.—In the article by Cope with this title in *THE JOURNAL* for June 24, in the first column on page 540, at the end of the third paragraph is the statement "For each per cent that the hematocrit is above the normal of 45, 50 cc. of plasma should be administered." This should have read "100 cc. of plasma should be administered."

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 3, 1944.

The Rehabilitation of the Injured

A feature of the present war is the increased extent to which the government is concerning itself with measures to remedy its consequences. This may be regarded as an example of the present socialistic trend of British politics. In 1941 the Ministry of Labor and National Service started a scheme for the training and resettlement of disabled persons. This scheme had two objectives: (1) to help those who had suffered recent disablement—whether through war service, in air raids or from other causes—to take up employment of a kind suited to their disability and (2) to help those whose disability was of earlier date to prove their capacity for useful work and play their part in the war effort. Everything is done under the scheme to get disabled people into the kind of employment best suited to their disability. A representative of the ministry, known as the disablement rehabilitation officer, visits all hospitals and service establishments from which discharges on medical grounds take place and interviews any person who has a disablement and who needs advice and help to find suitable employment. He gets a report from the medical authorities as to the nature of the disablement and the kind of employment and training which seems most suitable. In amputation cases a special report is obtained from the limb fitting surgeon at the center where the artificial limb is provided.

Training for a new occupation is provided when necessary. A special residential center has been set up to assist in the return to work of men who, following a period of hospital or other medical treatment, are not fit to take up employment or full time vocational training. Its object is to restore confidence and mental and physical fitness through healthy indoor and outdoor occupation. Vocational training is obtained for all persons whose disablement prevents them from resuming their normal occupation. Suitably qualified persons whose educational careers have been interrupted by war service are given assistance to continue their education. Allowances of money for maintenance during training are paid according to a scale which takes into account the existence of wife and children. No such scheme for the rehabilitation of the injured has ever been in force in previous wars.

The Control of Cross Infection in Hospitals

The prevention of cross infection in hospitals has recently received much attention here. A subcommittee of the Medical Research Council, consisting of experts on the subject, has made an important report which deals principally with children's wards, where the danger is greatest. They point out that the risk of cross infection is serious unless there are sufficient isolation units and nurses trained in the prevention of infection. Children should not be admitted to a hospital for trivial complaints if this can be avoided, and they should not be retained longer than necessary. The large, open, undivided ward should now be considered obsolete; structural subdivision into smaller units is the modern tendency. Nearly half the beds in hospitals for children should be in individual "cells" with walls extending from floor to ceiling, and the remainder should be in small units. These allow distribution of patients according to medical hazards rather than according to age, separation of the known infected from the uninfected, and grouping together of infectious patients from a common environment.

Nurses should be allocated according to cross infection hazards, the report recommends. There is obvious risk in employing in a milk kitchen nurses who are also on outpatient or

toilet duty, and in the not uncommon practice of employing "runners" between wards at night. The same considerations apply to other members of the staff and to arranging clinical courses for students. The admission of patients—particularly child, maternity and infectious cases—direct to open wards without preliminary examination is deplored in the report. The admitting medical officer should note the dates of previous infections, recent contacts and immunization. He should look for prodromal signs, nasal and aural discharges, tonsillitis, diarrhea and vomiting, skin disorders and similar evidence of infection. As soon as possible after admission, swabs should be taken from patients with upper respiratory infection, discharges or skin infections.

If "cell" accommodation is insufficient, selected patients should be nursed by the technic known as "bed isolation" or "barrier nursing," the report states. This technic should also be used in conjunction with cell isolation. Children should be immunized against diphtheria and whooping cough. As visitors may introduce infection, they should be limited and should not include children. They should wear masks and gowns. To control droplet infection, ventilation should be as free as possible, winter and summer, day and night, the committee declares. In doing surgical dressings or in feeding children under 1 year of age nurses should wear masks. To control dust borne infection, blankets and pillows should be gently handled. The bedclothes of 1 patient should not be placed on the bed of another or allowed to touch the floor. Impregnation of blankets with "technical white oil" reduces materially the number of bacteria scattered, it is stated. The floors of wards and passages, if of wood or covered with linoleum, should be treated with spindle oil. This prevents dust from rising during sweeping. Rubber, composition or concrete floors should be washed, vacuum cleaned or sprinkled with moist sawdust before sweeping. All dusters should be dampened with diluted "white fluid" (phenolic emulsion) before use. As dust is heavily contaminated with pathogenic bacteria, nurses should not undertake cleaning and ward maids should not undertake any nursing duties.

Rickets Not Increased in Spite of the War

It has been pointed out in previous letters that on the whole the health of the country has improved during the war. A report issued by the Ministry of Health shows that rickets, a disease of children at one time very prevalent in this country, has shown no increase during the war. It was comparatively rare before the war, but it was nevertheless possible, as the chief medical officer of the ministry states, that the downward trend of its incidence might have been checked. A "Report on the Incidence of Rickets in Wartime" by the British Pediatric Association shows that this has not occurred. The present position is regarded by the chief medical officer as due in no small measure to the efforts that have been made to maintain a high standard of nutrition in infants and young children by securing priorities for them in the foods and vitamin supplements essential for their growth and well being.

The investigation carried out by the British Pediatric Association included a clinical and x-ray examination of one wrist of 5,283 children between the ages of 3 and 18 months in twenty-three areas of Britain. The children were as far as possible well, having been selected from among those attending welfare centers or wartime nurseries. Of these only 106 showed x-ray evidence of rickets. A questionnaire was drawn up by Dr. Percy Stocks, medical statistician to the General Register Office and the Ministry of Health. He reports that the incidence of rickets shown radiologically in children between 3 and 14 months of age was 2.5 per cent in children up to the age of 6 months, 4 per cent during the first year of life and negligible after this. The clinical diagnosis of rickets showed great variability in different parts of Britain, being completely absent in some small towns but as high as 61 per cent in Sheffield.

the center of the steel industries. The correlation between the clinical and the radiologic diagnosis was poor. Only a small proportion of the clinically positive cases were confirmed radiologically. It was suggested that this result, far from throwing doubt on the value of clinical diagnosis, may be interpreted as a failure of radiology to detect all cases of rickets. But this view is refuted by the fact that clinical diagnosis failed to pick out half the cases of active rickets diagnosed by radiology. There are difficulties in diagnosis by either method, especially in the healing stage, and there is as much subjective influence in the radiologist's opinion as in that of the clinical observer. The severe type of rickets with deforming bone changes has disappeared from Britain, and this fact involves some modification of the clinical conceptions of rickets. It is suggested that a disturbance of calcification sufficient to indicate active rickets in a roentgenogram but not detected clinically, may need a new terminology.

BRAZIL

May 20, 1941.

Vital Statistics of Rio de Janeiro and São Paulo

Provisional vital statistics for the first quarter of the present year (mostly summer in the Southern Hemisphere) are now available for the two largest cities of Brazil—Rio de Janeiro, the capital city, and São Paulo, the most important industrial center of the country. These two cities differ as to size, climate and composition of population, the dissimilarities explaining, at least in part, the differences in vital statistics. The present calculated population of Rio de Janeiro is 1,927,000 inhabitants, while that of São Paulo is 1,399,000. The latter city has a much cooler climate and a lower percentage of colored inhabitants. During the first quarter of 1944 the annual birth rates were 21.14 for Rio de Janeiro and 25.74 for São Paulo. The death rate from all causes for Rio de Janeiro was 16.48 and for São Paulo was 9.31. For the age group under 1 year, for Rio de Janeiro there was an infant mortality rate of 178 per thousand live births against an infant mortality rate of 98 per thousand live births in the same age group for São Paulo. Of the total number of deaths registered for Rio de Janeiro, 30.53 per cent, or 5.03 per thousand of population annually, were due to infectious and parasitic diseases and for São Paulo 20.99 per cent, or 1.95 per thousand population annually from the same causes. On the basis of the number of deaths registered during the first quarter of the year the annual death rates from the most important communicable diseases were respectively for Rio de Janeiro and São Paulo typhoid 3.49 and 3.22 per hundred thousand of population, whooping cough 17.43 and 10.29, diphtheria 4.92 and 3.64, tuberculosis 293 and 103, influenza 45.54 and 14.36, measles 11.90 and 3.22, dysentery 20.72 and 18.44 and leprosy 5.33 and 0.21. For the same period the number of deaths from diarrhea and enteritis in the age group under 2 years was 1,109 for Rio de Janeiro and 633 for São Paulo, or respectively 13.80 per cent and 14.59 per cent of the number of deaths from all causes, which corresponds to annual death rates of 228 and 138 per hundred thousand of population.

Brief News

Under the chairmanship of Dr. Fernando Herrera Ramos, a Uruguayan Congress of Medicine is now being held in Montevideo. Brazilian and Argentine physicians have been specially invited. The main subjects to be discussed are arterial hypertension and rheumatic diseases. Among the papers presented to the congress are those of Drs. Waldemar Berardinelli, Moacyr Alvaro, Mariano Castex, Bernardo Houssay, Nicolas Romano, Pedro Cossio Arrillaga, Tomás Mariante and Granados Garcia.

For the first time candidates are being subjected to special examinations to be registered as "practical optometrists" and

authorized to sell, in all states of Brazil, spectacles with simple colored glasses, which have been sold up to now at almost every kind of store.

Dr. L. Pinheiro Guimarães has been appointed professor of pathology of the School of Medical Sciences of Rio de Janeiro. This school is independent of the University of Rio de Janeiro, where Dr. Pinheiro Guimarães began his teaching career.

The first South American Congress of Homeopathy was held recently at Porto Alegre, state of Rio Grande do Sul. One of the leading figures of this meeting was Dr. Ivano Duce of Uruguay. It is interesting to point out that the practice of homeopathy is not permitted in Argentina.

The Bahia Medical Association recently elected a new board of directors for the year 1944-1945. This board is composed of Drs. Adriano Pondé, Hosannah de Oliveira, Ezequiel da Costa, F. Carvalho Luz, Cicero A. da Silva, Domingos Saboia and Luis Cerqueira.

Dr. Madeira de Freitas, professor of medicine at the Fluminense Medical School of Niteroi, state of Rio de Janeiro, died recently at the age of 58. Besides teaching medicine, Dr. Madeira de Freitas was also an able writer whose books were highly appreciated in literary circles.

Dr. Nicolao Ciancio, a popular physician of the city of Rio de Janeiro, died recently at the age of 62. Dr. Ciancio, who was born in Italy, came to Rio de Janeiro with his parents, who died of yellow fever soon after their arrival. Overcoming many difficulties, young Ciancio struggled for his living, first as a newsboy, then as a newspaper reporter and finally as a journalist-physician. His column in the Rio de Janeiro *A Noite* was very popular, as he was the first doctor here to give medical information in the newspapers.

Dr. A. Murtinho Nobre, who had a large practice in Rio de Janeiro, died recently at the age of 65. After the death of Dr. Joaquim Murtinho, his uncle and the most famous of all homeopathic physicians of Brazil, twenty-five years ago, Dr. Murtinho Nobre was the leading homeopathist of the country.

Deaths

Dr. Helion Povia, professor of pathology at the University of Rio de Janeiro, died recently at the age of 45. Dr. Povia was considered one of the best professors of the medical school, where his intelligence, his culture, his enthusiasm for teaching and his integrity were greatly appreciated. Dr. Povia was a member of the National Academy of Medicine, where he won several prizes for specialized monographs written in competition with older and more experienced colleagues. One of his topics was cancer, the subject of several special postgraduate courses that he gave. Among his many medical books the best known are a textbook of pathology and an introduction to medicine.

Marriages

PETER W. WHEELER, Haverhill, Mass., to Miss Mary E. McCarthy of Manchester, N. H., in May.

SARAH HULDAH HOOVER, Richmond, Va., to Mr. George R. Jones of Jacksonville, Fla., June 10.

RICHARD LOOMIS OLIVER, Raleigh, N. C., to Miss Frances Christine Biles of Troy, June 10.

EDGAR JAMES MAXWELL JR., Atlanta, Ga., to Miss Edna Earle Shank of Augusta recently.

HAROLD P. WEAVER, Slatington, Pa., to Miss Regina Ezerski of Pittsburgh, Nov. 26, 1943.

CHARLES W. STRATTON JR., Lee, Mass., to Miss Marita J. Dick of Worcester, June 3.

Deaths

John Thomas Murphy ☉ prominent roentgenologist of Toledo and for thirteen years secretary of the Section on Radiology of the American Medical Association, died in St. Vincent's Hospital, Toledo, June 15, aged 58.

Dr. Murphy was born in Toledo April 15, 1885. He graduated at the Medical College of Toledo University in 1906. After postgraduate work at Cook County Hospital in Chicago, Dr. Murphy returned to Toledo to become associated with the late Dr. Julius Jacobson. He later taught histology and pathology at his alma mater.

Early in his career, Dr. Murphy became interested in radiology. In 1917 he accepted an appointment as director of the department of radiology at St. Vincent's Hospital, holding the position until his death. He was consultant to the Lucas County Hospital.

A specialist certified by the American Board of Radiology, Inc., Dr. Murphy held membership in numerous organizations, including the American Radium Society and the Radiological Society of North America. He had served as president of the American College of Radiology, the American Roentgen Ray Society, of which he had also been secretary, and the Academy of Medicine of Toledo and Lucas County. He held the office for two terms for the Detroit Roentgen Ray and Radium Society. He was a fellow of the American College of Physicians and of the American College of Radiology.

Dr. Murphy had been secretary of the Section on Radiology of the American Medical Association since 1932. In 1941 he received a Certificate of Merit from the Scientific Exhibit of the Association for his display on bone tumors. In 1937 he, with his associate Dr. Clarence E. Hufford, received a silver plaque for their exhibit of 600 x-ray plates showing results of treatment in bone diseases at the fifth International Congress of Radiology in Chicago and in 1942 a gold medal from the American Academy of Orthopaedic Surgeons for an exhibit on bone pathology. In 1941 he delivered the Hickey Memorial Lecture of the Wayne County Medical Society, Detroit, on "Use of X-Ray in the Treatment of Carcinoma of the Skin."

Long before pilots needed licenses to fly, Dr. Murphy flew his own plane. He was acquainted with many of the early fliers and was a sponsor of the Civil Air Reserve in Toledo. He maintained an interest in athletics since his college days when he had been a member of the track team and was a member of the American Amateur Athletic Association and president of the Toledo Figure Skating Club.

Chief among his numerous contributions to the literature were Dermoid Cysts in the Thorax, 1922; Bodies in the Lumen of the Appendix, 1922; A Complicating Factor in the Diagnosis of Chronic Upper Abdominal Diseases, 1925; Intracranial Calcifications, 1928; Influence Affecting the Future of Roentgenology, 1933; Nonsuppurative Osteomyelitis, 1935, and Irradiation Therapy in Breast Cancer, 1936.

Frank Albert Burton ☉ San Diego, Calif.; Denver Homeopathic College, 1904; Denver and Gross College of Medicine, 1906; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otolological Society and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; on the staffs of the San Diego County General Hospital and Mercy Hospitals, San Diego, and the Scripps Memorial Hospital, La Jolla, where he died April 25, aged 71, of coronary thrombosis.

Albert Lucian Abbott, Covington, Ky.; Kentucky University Medical Department, Louisville, 1902; died April 24, aged 76, of myocarditis.

John Valdora Adams, Kelly, La.; College of Physicians and Surgeons, Dallas, 1905; died in the Caldwell Hospital, Columbia, April 13, aged 65, of hypertension.

Clarence Alonzo Aplin, Ames, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1893; died April 5, aged 87, of pneumonia and hypertension.

David G. Austin, Laingsburg, Mich.; Detroit College of Medicine, 1894; died in the Edward W. Sparrow Hospital, Lansing, April 30, aged 82, of arteriosclerotic myocarditis.

Charles Marion Aves ☉ Houston, Texas; University of Texas School of Medicine, Galveston, 1907; fellow of the American College of Surgeons; professor of clinical surgery (honorary) at the Baylor University College of Medicine; a major in the medical corps of the U. S. Army, serving overseas during World War I; on the staffs of the Baytown Hospital, Baytown; Hermann Hospital and St. Joseph's Infirmary; medical director of the Humble Oil and Refining Company; died April 25, aged 62, of cerebral hemorrhage.

William Shirmer Barker, Clayton, Mo.; Missouri Medical College, St. Louis, 1890; formerly on the staff of the Bethesda General Hospital, St. Louis; died April 16, aged 80, of myocardial failure.

Omer Fouts Barnes, Arcola, Ill.; Kentucky School of Medicine, Louisville, 1890; served as mayor of Arcola; on the staff of the Douglas County Jannan Hospital, Tuscola; died April 18, aged 79, of coronary heart disease.

Conde Auguste Beucler, Tolo, Ore.; Keokuk (Iowa) Medical College, 1894; died in the Community Hospital, Medford, March 30, aged 75, of coronary occlusion.

Frank Probasco Bohn, Newberry, Mich.; Medical College of Indiana, Indianapolis, 1890; member of the Michigan State Medical Society; past president of the Luce County Medical Society; formerly village president and member of the school board; served three terms in Congress and two terms in the state senate; for twenty-two years chairman of the Luce County Republican Committee; for many years president of the Newberry State Bank; member of the board of the Newberry State Hospital from 1900 to 1920; died June 1, aged 77.

Joseph Aurelie Broussard, Port Arthur, Texas; College of Physicians and Surgeons, Memphis, 1911; member of the State Medical Association of Texas; on the staff of St. Mary's Hospital; died March 19, aged 59, of carcinoma of the prostate.

Joseph Addison Brown, Silex, Mo.; Hospital College of Medicine, Louisville, Ky., 1889; past president of the Lincoln County Medical Society; served as mayor of Silex; president and director of the Silex Savings Bank; partner, Silex Drug Company; died in the Missouri Baptist Hospital, St. Louis, April 12, aged 85, of senile dementia.

William M. Diamond, Dickson, Tenn.; University of Louisville (Ky.) Medical Department, 1890; served as magistrate for Dickson County; formerly on the staff of St. Thomas Hospital, Nashville; died April 11, aged 80.

James Frank Donaldson, Middleton, Mass.; Harvard Medical School, Boston, 1902; member of the Massachusetts Medical Society and the New England Pediatric Society; chief of medical staff, emeritus, Salem Hospital, and North Shore Babies' Hospital, Salem; died March 10, aged 66, of arteriosclerosis.

Henry Drey, Brooklyn; Long Island College Hospital, Brooklyn, 1920; member of the Medical Society of the State of New York; on the staff of the Lenox Hill Hospital, died April 4, aged 49, of hypertension.

George Field Enoch ☉ Philadelphia; University of the South Medical Department, Sewanee, Tenn., 1898; physician for the Philadelphia County Prison; served on the staff of the Frankford Hospital; died in the Graduate Hospital of the University of Pennsylvania, April 3, aged 67, of uremia.

James Joseph Fleming, New York; Yale University School of Medicine, New Haven, 1922; formerly assistant professor of clinical surgery at the New York Post-Graduate Medical School, Columbia University; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; served as attending surgeon, New York City Department of Correction; assistant attending surgeon at the New York Post-Graduate Hospital, where he died April 16, aged 47.

Henry Francis Goeken, Baltimore; Hahnemann Medical College and Hospital of Philadelphia, 1921; member of the Medical Society of the State of Pennsylvania; served during World War I; formerly on the staff of the Hanover Hospital, Hanover, Pa.; died in St. Joseph's Hospital April 16, aged 52, of acute coronary occlusion.

Ralph Augustus Hatch ☉ Boston; Harvard Medical School, Boston, 1906; specialist certified by the American Board of Ophthalmology; member of the New England Ophthalmological Society; served during World War I; on the staffs of the Massachusetts Eye and Ear Infirmary, Massachusetts General, Children's and Boston State hospitals and the Florence Crittenton Home and Hospital; died in the Brookline Hospital, Brookline, April 1, aged 62.

Vernon Francis Kelly, Baltimore; University of Maryland School of Medicine, Baltimore, 1904; on the staffs of St. Anne's and St. Joseph's hospitals; died in the Johns Hopkins Hospital, March 5, aged 60, of coronary occlusion.

Lincoln S. Lacy, Pittsfield, Ill.; Missouri Medical College, St. Louis, 1898; member of the Illinois State Medical Society; served several terms on the city council; on the staff of the Illinois Community Hospital; died April 10, aged 83, of carcinoma of the liver.

Lucius Edgar Lawler, Miami, Fla.; Atlanta College of Physicians and Surgeons, 1901; died April 8, aged 71, of atherosclerosis.

Alice Farnham Leader, Winter Park, Fla.; Woman's Medical College of Pennsylvania, Philadelphia, 1884; died in the Florida Sanitarium and Hospital, Orlando, April 20, aged 81, of myocardial infarction.

Oscar Clare Lohr, Churdan, Iowa; Barnes Medical College, St. Louis, 1896; member of the Iowa State Medical Society; vice president of the First State Bank; died in Jefferson April 9, aged 71, of coronary thrombosis.

Harold Hamilton Longsdorf, Dickinson, Pa.; College of Physicians and Surgeons, Baltimore, 1882; member of the Medical Society of the State of Pennsylvania; served as school director and past president of the Cumberland County School Directors Association; physician for the county prison for many years; a director of the Farmers Trust Company at Carlisle; on the staff of the Carlisle Hospital, Carlisle; died April 28, aged 85, of cerebral hemorrhage.

Arthur Hubert Longstreet, Brooklyn; University of Vermont College of Medicine, Burlington, 1900; member of the Medical Society of the State of New York; served on the staffs of the Norwegian, Victory Memorial and Bay Ridge hospitals; died April 4, aged 71, of heart disease.

George Davis Lowry * Detroit; College of Physicians and Surgeons, New York, 1894; member of the Ohio State Medical Association; formerly a member of the staff of Peiping Union Medical College and of the Methodist Hospital in Peking, China; served as physician at the Ohio Wesleyan University, Delaware, Ohio; died in the Toledo Hospital, Toledo, Ohio, April 9, aged 76, of a fractured skull received in an automobile accident.

Edward Joseph Lynch, Detroit; St. Louis University School of Medicine, 1913; member of the Michigan State Medical Society; served in the medical corps of the U. S. Army during World War I; on the staff of St. Joseph's Mercy Hospital; died April 18, aged 59, of cerebral hemorrhage.

Frederick L. Lyons, Boston (licensed in Massachusetts in 1909); served on the staffs of the Carney Hospital and St. Elizabeth's Hospital, where he died April 28, aged 58, of coronary thrombosis.

James Lewis McAuslan, North Grafton, Mass.; Harvard Medical School, Boston, 1899; member of the Massachusetts Medical Society, American Psychiatric Association and the New England Society of Psychiatry; specialist certified by the American Board of Psychiatry and Neurology, Inc.; served during World War I; senior physician at the Grafton State Hospital from 1919 to 1943; died in Boston March 22, aged 69, of angina pectoris.

John Thomas McFarlin, Williams, Ind.; University of Louisville (Ky.) Medical Department, 1894; member of the Indiana State Medical Association; past president of the Lawrence County Medical Society; served during World War I; died in the Dunn Memorial Hospital, Bedford, April 18, aged 76, of chronic myocarditis.

Frank Lynn McGahey, Calhoun City, Miss.; University of Tennessee College of Medicine, Memphis, 1916; member of the Mississippi State Medical Association; past president of the Northeast Mississippi Thirteen Counties Medical Society; since June 1, 1942 director of Grenada County Health Department; formerly health officer of Calhoun County; died in a hospital at Memphis, Tenn., April 22, aged 51, of cerebral hemorrhage.

Frank Wickham Mallalieu, Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; for many years associated with the child welfare service of the Mother's Institute; found dead April 12, aged 75, of heart disease.

August Albert Meyer, Alma, Kan.; University Medical College of Kansas City, Mo., 1904; also a pharmacist; county health officer; died March 19, aged 67, of carcinoma.

Gustavus Adolphus Meyer, Springfield, Mo.; St. Louis College of Physicians and Surgeons, 1895; Barnes Medical College, St. Louis, 1897; died April 2, aged 81, of coronary thrombosis and bronchopneumonia.

Gilbert Bertram Meyers * Pittsburgh; University of Pittsburgh School of Medicine, 1917; assistant professor of medicine at his alma mater; served as a lieutenant in the medical corps of the U. S. Navy during World War I; senior staff member of the Mercy Hospital, where he died April 9, aged 54, of cerebral hemorrhage.

William Rankin Miller, Danville, Ill.; Western Pennsylvania Medical College, Pittsburgh, 1892; for seven years contract physician for the Pittsburgh Steel Company; died in the Lakeview Hospital April 5, aged 77, of cerebral hemorrhage.

Landon Clay Moore, Reynolds, Ill.; Rush Medical College, Chicago, 1886; member of the Illinois State Medical Society;

member of the "Fifty Year Club" of the state society; formerly on the staff of St. Luke's Hospital, Davenport, Iowa; died in the Mercy Hospital, Davenport, April 10, aged 84, of uremia and chronic nephritis.

Amanda Taylor Norris, Baltimore; Woman's Medical College of Pennsylvania, Philadelphia, 1880; member of the Medical and Chirurgical Faculty of Maryland; died in a nursing home in Pikesville April 27, aged 95, of arteriosclerosis.

John Palkovich, Hammond, Ind.; University of Kolozsvár, Hungary, 1894; died April 21, aged 81, of acute dilatation of the heart and myocarditis.

Joseph Baxter Patrick, Brunswick, Ga.; Kentucky University Medical Department, Louisville, 1904; member of the Mississippi State Medical Association; on the staff of the J. A. Jones Construction Company Clinic and chief medical inspector for the company; died April 5, aged 64, of heart disease.

Hans Arthur Paulsen, Chicago; Chicago College of Medicine and Surgery, 1912; member of the Illinois State Medical Society; on the courtesy staff, Martha Washington Hospital, where he died April 11, aged 58, of acute nephritis.

Percival Pearce, Waukegan, Ill.; College of Physicians and Surgeons of Chicago, 1896; for many years a druggist; died May 16, aged 76, of cerebral hemorrhage.

Thomas Francis Xavier Phelan, Chicago; Loyola University School of Medicine, Chicago, 1917; on the staff of St. Anne's Hospital; died May 10, aged 58, of coronary thrombosis.

Edward Ferguson Pickford * Washington, D. C.; Albany (N. Y.) Medical College, 1895; served as vice president of the City Bank; on the courtesy staffs of all local hospitals; died May 6, aged 75, of cerebral hemorrhage.

Eugene H. Pitts * Sacramento, Calif.; Chattanooga (Tenn.) Medical College, 1900; served as president of the Eugenics Society of Northern California; honorary member, Sociedad Eugenesia de Mexico; member of the American Genetic Association and the Eugenics Society of Great Britain and London; on the staffs of the Sutter General and Mercy hospitals; for many years a director of the Y. M. C. A.; died May 1, aged 73.

Archie Leonard Poppewell, Anton, Texas; Baylor University College of Medicine, Dallas, 1912; member of the State Medical Association of Texas; died in the Littlefield Hospital and Clinic, Littlefield, March 22, aged 56, of coronary thrombosis.

Edwards Hyndshaw Porter * Tiffin, Ohio; Detroit College of Medicine, 1900; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the Northwestern Ohio Medical Association; served during World War I; chief of staff, Mercy Hospital, where he died May 14, aged 71, of coronary occlusion.

James Miller Quinn * Passed Assistant Surgeon, Lieutenant Commander, U. S. Navy, retired, Beckley, W. Va.; Baltimore Medical College, 1911; U. S. Naval Medical School; entered the U. S. Navy in 1917; served during World War I; retired Dec. 5, 1921; died January 18, aged 55.

John F. Reid, Buchanan, Ga.; Atlanta Medical College, 1892; member of the Medical Association of Georgia; served as mayor of Buchanan; represented Haralson County in the state legislature for two terms; county treasurer; died in Carrollton April 3, aged 75, of cardiovascular renal disease.

Fred Rice, Lancaster, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; died in St. Joseph's Hospital April 23, aged 68, of a skull fracture and injuries received when struck by a truck.

Nelson Guernsey Richmond, Fredonia, N. Y.; Bellevue Hospital Medical College, New York, 1880; member of the Medical Society of the State of New York; died in the Florida Sanitarium and Hospital, Orlando, April 18, aged 87, of lobar pneumonia.

Norman Roberts * Surgeon, U. S. Public Health Service, retired, West Chester, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; Hahnemann Medical College and Hospital of Philadelphia, 1898; U. S. Naval Medical School, 1922; appointed an assistant surgeon in the U. S. Public Health Service on July 25, 1903 and retired on Dec. 9, 1930; died in the Chester County Hospital April 18, aged 67, of acute congestive cardiac failure.

Leo Saporito, Kaplan, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; member of the Louisiana State Medical Society; a member of the draft board during World War I; formerly coroner of Vermillion Parish; died April 13, aged 61, of coronary thrombosis.

Raymond J. Schmid * New Ulm, Texas; University Medical College of Kansas City, Mo., 1901; past president

of the Austin County Medical Society; died March 22, aged 67.

John William Schulze, Minneapolis; University of Minnesota Medical School, Minneapolis, 1943; served a residency at the Minneapolis General and the Fairview hospitals; died in the University Hospitals February 2, aged 26, of hypostatic bronchopneumonia.

Clark Edwards Sharp, Columbus, Ohio; Starling Medical College, Columbus, 1896; member of the Ohio State Medical Association; a captain in the medical corps of the U. S. Army, serving for a time at Base Hospital number 64, near Verdun, France; died April 2, aged 69, of coronary thrombosis.

George Henry Smith, East Orange, N. J.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1912; member of the Medical Society of New Jersey; a captain in the medical corps of the Canadian Army during World War I and for ten years a major in the reserve; a member of the staffs of St. Michael's Hospital, Newark, St. Mary's Hospital and the Orange Memorial Hospital, Orange, where he died April 15, aged 60, of cerebral thrombosis and heart disease.

George Seeley Smith Ⓢ Shaker Heights, Ohio; Harvard Medical School, Boston, 1893; formerly associate professor of medicine at the Cleveland College of Physicians and Surgeons; served as examiner for a number of life insurance companies; died in the Charity Hospital, Cleveland, April 8, aged 77, of edema of the lungs, following an operation.

Harvey Smith, Spokane, Wash.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1897; member of the Washington State Medical Association; on the staffs of the Sacred Heart Hospital and the Deaconess Hospital, where he died March 29, aged 70, of carcinoma.

Leonard Marshall Smith Ⓢ Oshkosh, Wis.; Northwestern University Medical School, Chicago, 1926; entered the Mayo Foundation, Rochester, Minn., as a fellow in surgery Oct. 1, 1926 and in October 1929 was appointed first assistant in surgery; served during World War I; fellow of the American College of Surgeons; on the staff of the Mercy Hospital; died April 13, aged 47.

William Sidney Smith Ⓢ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1905; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; a captain in the medical corps of the U. S. Army during World War I; fellow of the American College of Surgeons; past president of the New York and Brooklyn Obstetrical societies; chief attending gynecologist and obstetrician, Brooklyn Hospital; died April 18, aged 61, of coronary disease.

Clinton J. Sprinkell, Russellville, Ill.; Hospital College of Medicine, Louisville, Ky., 1900; member of the Illinois State Medical Society; died April 21, aged 71, of heart disease and tabes dorsalis.

Oscar Wayne Sprouse, Sulphur, Okla.; Barnes Medical College, St. Louis, 1903; died February 24, aged 71.

Warren L. Stamper, Indianapolis; Kentucky School of Medicine, Louisville, 1892; also a dentist; died April 2, aged 73, of cerebral hemorrhage.

Chester Arthur Stebbins, Lexington, Ky.; Barnes Medical College, St. Louis, 1911; served in the medical corps of the U. S. Army during World War I; died April 10, aged 60, of asthma.

Carl Floyd Stevens, North Hollywood, Calif.; Medical College of Virginia, Richmond, 1940; member of the California Medical Association; died March 1, aged 50.

Sardine Graham Stone, Nanafalia, Ala.; Medical College of Alabama, Mobile, 1887; member of the Medical Association of the State of Alabama; died in Folly April 7, aged 77, of congestive heart failure, hypertension and arteriosclerosis.

Benson R. Sumner, Armada, Mich.; Detroit College of Medicine, 1902; a captain in the medical corps of the U. S. Army during World War I; for many years on the staff of the Providence Hospital, Detroit; died April 10, aged 72, of coronary occlusion and heart block.

Fred Traganza, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1894; Baltimore Medical College, 1895; member of the Medical Society of the State of Pennsylvania; died March 24, aged 73.

George C. Trimble, East Point, Ga.; Atlanta Medical College, 1888; member of the Medical Association of Georgia; served as city physician and on the East Point Council; formerly in charge of the Georgia Baptist Orphanage; for many years local surgeon for the Central of Georgia Railway; died April 9, aged 80, of heart disease and diabetes mellitus.

Harmon Albert Vedder, New York; College of Physicians and Surgeons, New York, 1891; served during World War I;

died in St. Luke's Hospital April 5, aged 76, of pulmonary edema.

Joseph Frederick Wood Ⓢ Portland, Ore.; University of Oregon Medical School, Portland, 1900; fellow of the American College of Surgeons; formerly secretary and member of the Board of Medical Examiners; died May 17, aged 67.

William Henry Lee Woodyard, Judsonia, Ark.; Memphis (Tenn.) Hospital Medical College, 1894; local surgeon for the Missouri Pacific Railroad; for many years president of the Farmers and Merchants Bank; died March 26, aged 78, of coronary occlusion.

Homer Woolery, Bloomington, Ind.; State College of Physicians and Surgeons, Indianapolis, 1907; member of the American Academy of Pediatrics; served during World War I; died in Hollywood, Fla., April 22, aged 71, probably of coronary thrombosis.

DIED WHILE IN MILITARY SERVICE

John Jacob Bortz, Allentown, Pa.; Temple University School of Medicine, Philadelphia, 1930; member of the Medical Society of the State of Pennsylvania; served as an examining physician at the Allentown Induction Center; a member of the staff of the Sacred Heart Hospital; commissioned a captain in the medical corps, Army of the United States, on Oct. 16, 1942; began extended active duty on Oct. 31, 1942; died in San Francisco May 21, aged 40.

Henry Thomas Davis Jr., Galveston, Texas; Howard University College of Medicine, Washington, D. C., 1937; formerly assistant in pathology at his alma mater; served an internship at the Freedmen's Hospital, Washington, D. C., and a residency at the Flint-Goodridge Hospital of Dillard University, New Orleans; a first lieutenant in the medical reserve corps of the U. S. Army; died in the Fitzsimons General Hospital, Denver, March 31, aged 32, of pulmonary tuberculosis.

Sidney Chase Graves Ⓢ Milton, Mass.; Harvard Medical School, Boston, 1929; fellow of the American College of Surgeons; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the New England Obstetrical and Gynecological Society and the Boston Obstetrical Society; formerly assistant in gynecology at his alma mater; served as assistant visiting surgeon to the Free Hospital for Women, Brookline; commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve, July 20, 1942; began extended active duty on Sept. 18, 1942 at the U. S. Naval Hospital in Chelsea; died in the Pacific area May 14, aged 42, from a knife wound of the neck.

Alexander Vayle Harrison, San Pedro, Calif.; University of Oklahoma School of Medicine, Oklahoma City, 1939; served an internship at the Los Angeles County Hospital, Los Angeles; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 6, 1939; began extended active duty on Nov. 18, 1940; later promoted to captain; died in New Britain March 4, aged 29, of scrub typhus.

• **Jack Robert Hughes** Ⓢ Captain, M. C., U. S. Army. San Francisco; Stanford University School of Medicine, San Francisco, 1941; commissioned a first lieutenant in the medical corps of the U. S. Army; began active duty on July 3, 1941; later promoted to captain; died in the Percy Jones General Hospital, Battle Creek, April 29, aged 30, of intestinal obstruction, adhesions due to gastric resection performed for peptic ulcer.

Edgar David Riley, Terrell, Texas; Baylor University College of Medicine, Dallas, 1937; member of the State Medical Association of Texas; served on the staff of the Alexander Hospital; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on May 31, 1937; medical reserve corps; began extended active duty at later promoted to captain; served as chief surgeon in Camp Berkeley, Jan. 22, 1941; served as chief surgeon in a field hospital in India for sixteen months; died in the Brooke General Hospital, Fort Sam Houston, February 17, aged 33, of brain tumor.

David Earl Vogan Jr., Mercer, Pa.; University of Pittsburgh School of Medicine, 1942; served an internship at the Presbyterian Hospital, Pittsburgh; commissioned a first lieutenant in the medical corps, Army of the United States, on June 1, 1942; began active duty on July 3, 1943; died in New Guinea April 29, aged 25, of acute hemorrhagic purpura.

Bureau of Investigation

TWO CALIFORNIA RHEUMATISM FRAUDS

One from San Francisco—"Unipathic" Nostrums

The "Unipathic Medicines," recommended chiefly for arthritis, were sold through the mails from San Francisco by the Maxwell Sales Company, whose manager was a J. W. Spiker. These promoters, on learning that the Post Office Department was investigating their scheme, wrote that department in June 1943 that they were discontinuing their business and offered to agree in writing to do so, apparently hoping to avoid the issuance of a fraud order, which would delar them from using the mails. The Department refused the offer and set a time for the hearing on the charge of using the mails to defraud. On the date set, a government chemist testified that his analysis of the seven Unipathic nostrums showed the following:

"R No. 1," labeled as a "diuretic alternative stomachic tonic"—a brownish red solution of alcohol (21 per cent), saw palmetto, stillingia root, black cohosh, poke root and sherry wine, but lacking the aconite declared on the label

"R No. 2," labeled as a laxative—yellow-coated tablets containing belladonna, cascara, aloin, podophyllin and ginger.

"R No. 3," labeled as a rubbing oil—about equal amounts of turpentine, kerosene and paraffin oil, with wintergreen odor.

Unipathic Tablets, R A, B, C and D, averaged 99.5 per cent of milk sugar, traces of starch and infinitesimal amounts, if any, of the various drugs of the homeopathic type, too numerous to detail here, that were claimed on the label.

Another government witness, an authority on homeopathic medicine, testified, among other things, that the two general types of arthritis, specific and nonspecific, would not respond to the treatment in question, since the proper therapy must be based on the individual patient and his need, and hence no single type of treatment would suffice in all cases. The Post Office Department accordingly issued a fraud order on Oct. 5, 1943 against the Maxwell Sales Company, J. W. Spiker, Manager, and their officers and agents.

On Oct. 9, 1935 a jury in a California district federal court found Joseph W. Spiker, Frank W. Kimball and the Melatol Laboratories of Oakland, Calif., guilty of violating the National Food and Drugs Act, and a total fine of \$1,200 and costs was imposed. The case involved the shipping in interstate commerce of a consignment of "Melatol," the package and enclosed circular of which falsely and fraudulently represented the nostrum (which was nothing but crude oil) as a remedy for diabetes, stomach ulcer, Bright's disease and some other disorders. In October 1936 the California authorities reported that J. W. Spiker once had done business under the name "National Diabetic Clinic" but was then (1936) associated with a San Francisco outfit variously called the Mellow Tablet Company, the San Francisco Mel-O-Tab and the Mel-O-Tab Laboratories, putting out "Mel-O-Tabs" for stomach ulcer and "Naz-ol for Catarrh, Sinus, Asthma and Hay Fever."

And from Los Angeles—"A B C" Nostrums

Los Angeles, the happy hunting ground for many types of quackery in medicine, religion and politics, was the home of a concern operating under the names "American Mutual Health Association" and "ABC Preparations Company," with one R. P. Probasco designated as general manager. Through the mails they sold what they called "A B C Preparations" which, when taken singly or together, according to directions, in conjunction with "diet charts" and "instruction sheets," were represented to "go to the root of" and permanently "eradicate" and "cure" all forms of rheumatism, sciatica and arthritis; this, regardless of the supposed hopelessness of the case or the fact that the customer had previously tried "everything" without benefit. Further, these products were represented to overcome high blood pressure and kidney, bladder and prostate disorders.

And what were these "cures," promoted by extravagant claims and glowing testimonials? At the hearing of the case, held on July 26, 1943, a chemist of the Food and Drug Administration testified for the government that "Preparation A" was chiefly water, with less than 1 per cent each of hydrochloric and nitric acids; that "B" contained 36 per cent of alcohol and small

amounts of Jamaica dogwood and cinicifuga, and that "C," in powder form, was a mixture of phenolphthalein, senna, sulfur and cream of tartar.

Another government witness, a physician who has had experience in the treatment of arthritis and allied conditions and of the other diseases and symptoms described in the "A B C" advertising, testified as to causes and manifestations of arthritis, as well as other painful chronic diseases which are sometimes confused with it. He showed that different cases of arthritis may present varying degrees of inflammation, swelling, deformity and pain, according to the age, weight and other conditions of the patient, and also are influenced by weather and climatic conditions, as well as the complications of accompanying diseases. In many cases, he testified, the symptoms of arthritis may disappear entirely with the medication or change of diet, whereas in others they may become worse, regardless of treatment. Certainly, he said, there is no one treatment suitable for all of the many forms and conditions of this disorder, and the proper therapy must be based on the causative condition. Some cases require exercises, others rest, some a reducing diet and others a strengthening diet, whereas some call for surgery. He showed that there are no known drugs which will repair the damage done by arthritis to the bones and cartilage of the joints. The witness also discussed the other claims for the preparations, and the presumable actions of the latter as based on their respective compositions, and revealed the worthlessness of the formulas for the conditions in question. The respondents neither put in an appearance nor sent their attorney to represent them at the hearing. The Post Office Department found that the business was a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, in violation of the laws of the United States, and on Nov. 24, 1943 a fraud order was issued, debaring from the mails the American Mutual Health Association, ABC Preparations Company, R. P. Probasco, and their officers and agents.

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

"Formula Book" and "Brains Boiled Down."—These were titles of publications issued by Ernest L. Fantus, trading as Elfeo Service, Chicago, and contained formulas for various disorders. In May 1943 Fantus stipulated with the Federal Trade Commission that he would cease representing that products compounded in accordance with his formulas designated "Eczema Remedy," "Croup & Pneumonia Salve—Vapor Jelly for Inhalation," "Skin Lotion for Pimples, Blackheads, Etc." and "To Prevent Hair Falling Out" are effective treatments for the conditions indicated in those names. Previously Fantus had issued a booklet entitled "Schierl's System of Beauty Culture," which also contained formulas, and on Nov. 24, 1938, he stipulated with the Federal Trade Commission that he would cease representing that products compounded from these recipes would insure perfect skin, cure dandruff, promote hair growth, remove superfluous hair and freckles, keep arms white as snow and make hands soft and velvety.

Modern Eyes Mascara.—That this is the fastest selling brand of mascara and, when applied with the spiral brush which accompanies it, will coat all sides of the eyelashes rather than the under side only, were misrepresentations which Modern Cosmetics, Inc., of Chicago agreed to discontinue in its advertising in a stipulation that it entered into with the Federal Trade Commission in May 1943.

Vitamin-Quota.—This is put out by the Associated Laboratories, Inc., Long Island City, N. Y. In May 1943 this concern stipulated with the Federal Trade Commission to discontinue advertising misrepresentations that it is impossible or extremely difficult to obtain adequate intake of vitamins from ordinary foods, that conditions such as vague aches and pains, fatigue, lack of resistance to colds, nervousness, poor appetite, poor digestion, or lack of energy are necessarily symptomatic of vitamin deficiencies, and that the ingestion of Vitamin Quota capsules will relieve, remedy or correct such conditions or result in a superior state of health.

Correspondence

FAILURE OF THE SWEAT MECHANISM IN THE DESERT

To the Editor:—It was with interest that we read Captains Wolkin, Goodman and Kelley's article "Failure of the Sweat Mechanism in the Desert: Thermogenic Anhydrosis" (*THE JOURNAL*, February 19, p. 478). The reason for our interest is that we have observed 2 patients who presented the same syndrome. These men, however, were not subjected to the hot dry climate of the desert but to the hot highly humid climate of the South Pacific.

The first patient who came to our attention was a cook who had been in the tropics about seven months, where the temperature is high and the humidity is constantly near the saturation point. In addition to being exposed to this extreme heat, he carried out his duties as a cook. He was in good health and sweated in a normal fashion for the first six months. Then he noticed that in a short time he stopped sweating from the neck down and developed a dry scalliness of the skin. Associated with this was generalized weakness. Examination at this time showed a striking distribution of sweating. The day of examination was extremely hot, so that all of the examiners and the people in the dispensary were sweating profusely. This man was sweating in the same manner only about the head and neck. At the base of the neck the sweating stopped abruptly. The rest of the body was dry. Examination of the axillae and inner aspects of the groins showed the skin likewise perfectly dry. The skin presented a nondescript, dry, scaling, slightly erythematous eruption. There was no evidence of ichthyosis. He appeared weak and pale. Physical examination otherwise revealed nothing of importance. He was sent to a hospital in a cooler climate. On examination there nothing unusual was found. After two weeks of rest he began to sweat normally.

The second patient also was in the same type of climate; namely, hot and highly humid. He had no particular difficulties for the first four months; then he began to notice weakness while working and the appearance of a dry, scaly eruption and soon after this the failure to sweat. Because of the weakness that he developed on the slightest exertion he also was sent to a hospital in a cooler climate. Examination there showed nothing unusual except the anhydrosis. After three weeks of rest he was sweating normally and felt much stronger.

These 2 cases follow closely those described by the authors, with spectacular sweating of the face and neck, which stops abruptly, the rest of the body remaining dry. The eruption over the body is very similar to the stationary "goose flesh" that they describe; in other words, a dry papulofollicular, nonerythematous eruption. We were unfortunately unable to study their cases further. We feel that the authors have described a unique form of anhydrosis and that our patients also fall into this group.

The one difference between their patients and ours is that of climate. Their patients were subjected to extreme desert heat with low humidity, and ours to tropical heat with high humidity. It would seem, therefore, that only the high temperature plus some unexplained failure of the sweat mechanism are the principal factors in bringing out this syndrome.

Undoubtedly, with more troops being subjected to high temperatures over long periods of time, more of these cases will be seen. The only apparent treatment is removal to a cooler climate.

Further investigation as to the cause of this form of anhydrosis should be carried out.

FREDERICK G. NOVY JR.,

Lieutenant Commander, MC-V(S), U.S.N.R.

JOSEPH H. RAMSEY,

Lieutenant, MC-V(G), U.S.N.R.

SUGAR A "DILUTING" AGENT

To the Editor:—The Council on Foods and Nutrition (*THE JOURNAL*, Nov. 7, 1942, p. 763) gave as its view that "the consumption of sugar and of other relatively pure carbohydrates has become so great during recent years that it presents a serious obstacle to the improved nutrition of the general public." It was emphasized that refined sugar is a food deprived of vitamins and minerals; however, "if sugar could be always used only as a means of making highly nutritious foods like milk or whey more appetizing, much less odium would attach to it than does. . . . But even here one is essentially 'diluting with calories' the food which is sweetened."

The Council thus presents the concept of sugar "diluting with calories" the foods of our dietary. It seems we should study the full meaning of this concept, what it implies and note some of the biochemical events it involves as they appear to be related to our national health and war effort.

From the Council report it is made clear that when sugar is "diluting with calories" it is displacing nutritionally superior foods from the dietary, while at the same time it is increasing the requirements of nutrients in the foods displaced. Vitamins B₁, riboflavin and niacin are necessary for the oxidation of dextrose. Sugar does not supply these vitamins, yet it increases their requirements. When "diluting with calories" sugar is thus using vitamins from other foods or from the reserves of body tissues. Wilder (*Handbook of Nutrition*, *THE JOURNAL*, Oct. 17, 1942, p. 531) expressed the idea in these words: "Sugar is not among the recommended foods. Its recent rationing will not provoke a hardship, for sugar supplies nothing in nutrition but calories, and the vitamins provided by other foods are sapped by sugar to liberate these calories."

Cowgill (*THE JOURNAL*, Dec. 9, 1939, p. 2151) pointed out that there is an increased requirement of other food essentials like calcium, phosphorus and iron with an increase of calories. We may say, then, that sugar "diluting with calories" decreases the vitamin (or other nutrient)/calory ratio and increases the difficulty of obtaining a diet nutritionally adequate to meet the daily allowances recommended by the Food and Nutrition Board of the National Research Council (*THE JOURNAL*, June 7, 1941, p. 2601).

Little concern would be felt for the role of sugar as a "diluent" of foods and nutrients and a "sapper" of stored vitamins if only about 1 ounce (120 calories) per person daily were consumed, as was the case a hundred years ago. However, according to Gubin (*Hygeia*, January 1944, p. 15), the monthly per capita civilian consumption of sugar as food for 1935-1939 averaged 8 pounds (or 483 calories per person daily); for 1942 it was 7½ pounds (452 calories daily); for 1944 it is estimated to average 6½ pounds (or about 400 calories per person daily).

Four hundred calories of sugar consumed by a person on a diet of 2,000 calories represents a "dilution" with calories of 20 per cent. The diets of many people contain less than 1,800 calories per day; as, for example, 8.8 per cent of the aircraft workers in southern California (Vichl, Dorothy G.: *Milbank Memorial Fund Quart.* 20, October 1942). Even on a 4,000 calory diet the 400 calories of sugar dilutes the nutrients 10 per cent. Probably if the 400 calories of sugar were supplied by superior foods, all the nutrients would be more "concentrated" in the diet by 10 or 20 per cent, depending on whether the diet contained 4,000 or 2,000 calories.

It may sound superficial to say that "diluting" our foods with this great consumption of sugar is "diluting" the physical strength, national unity and war effort of our country, yet the Council on Foods and Nutrition of the American Medical Association (*THE JOURNAL*, Nov. 7, 1942), the Committee on Nutrition in Industry of the National Research Council (Report and Circular Series No. 110, April 1942) and members participating in the Symposium on Nutrition in Industry at the Annual Congress on Industrial Health (e. g. see discussion).

Wilder and of Pett, *THE JOURNAL*, March 13, 1943, pp. 869-871) have already expressed concern over the consumption of sweetened carbonated beverages and candy by workers in industrial plants.

It seems to me that more publicity should be given to this concept of sugar as a "diluting" agent; and more research is needed to find out the extent of harm our present consumption of sugar is causing.

Our patients and the general public must be made to realize that, while sugar supplies energy, it also "dilutes," weakens with calories, and that other carbohydrates and all proteins and fats are sources of energy.

RAY M. MOOSE, M.D., San Bernardino, Calif.

DIAGNOSIS OF EARLY SYPHILIS

To the Editor:—Clinical teaching has always stressed the fact that a painless sclerotic solitary ulcer or "hard chancre" is the typical primary lesion of syphilis. While it is true that all textbooks and teachers allow for some variation in the clinical appearance of the initial local sore, my personal observation is that its characteristics, somewhat like those of later syphilitic manifestations, are more protean than is generally considered by our profession.

In several years of both military and private practice I have had occasion to see relatively few cases of early syphilis. But of 11 cases that my associates and I were able to confirm positively by dark field examinations only 3 presented the classic type of primary lesion. The 8 others resembled ordinary chancroidal or balanitic ulcerations; they were not indurated, often were multiple and sometimes were painful. The most recent case in my personal experience was almost, and perhaps hardly inexcusably, overlooked as syphilitic, for the patient presented the typical picture of an ordinary nonspecific balanoposthitis complicating a phimosis with several tender ulcerated areas on the preputial mucosa and, furthermore, he maintained that he had had the same condition several times in the past. Only the history of recent exposure prompted me to have a dark field examination made, and it was quite a surprise to receive a laboratory report that the smear was found teeming with *Treponema pallidum*.

This naturally brings to mind the important question How many of the latent or advanced cases of syphilis we find were not detected in their early, more easily treated, stage simply because the primary lesion was so atypical or minor as not even to suggest the ruling out of syphilis to the examiner? If the threat of syphilis to mankind is to be further reduced, not only must a high "index of suspicion" be maintained on the part of the individual practicing physician but an abrupt *volte face* is in order on the part of our clinical teachers to emphasize duly the varied appearance of initial syphilitic lesions. Only thus can the practitioners of medicine be influenced to subject each and every clinical case presenting a genital ulcer of any description to the trustworthy oracle of the dark field laboratory examination.

JEROME M. SPATZ, Captain, M. C., A. U. S.

JONATHAN FOLTZ, M.D., SURGEON GENERAL OF THE NAVY

To the Editor:—On page 278 of the May 27 issue of *THE JOURNAL* there is an editorial comment on the recent celebration of the Lancaster city and county medical societies. It speaks of Dr. Jonathan M. Foltz as being Surgeon General under President Grant. Dr. Foltz was Surgeon General of the U. S. Navy, and I am sure there was a Surgeon General of the U. S. Army at the same time, so that this branch of the service should have been designated. I happened to notice this because in

writing up my grandfather's diary I used a biography of Dr. Foltz, who during the Civil War was ship surgeon on Farragut's flag ship while my grandfather was paymaster on one of the other vessels in the same fleet.

STANLEY B. WELD, M.D., Hartford, Conn.
Managing Editor, *Connecticut State Medical Journal*.

BILATERAL OOPHORECTOMY WITH RADICAL OPERATION FOR CANCER OF THE BREAST

To the Editor:—Your editorial on "Bilateral Oophorectomy with Radical Operation for Cancer of the Breast" in the May 20 issue, was interesting.

Oophorectomy may favorably influence the control of mammary cancer, but such a blunt statement is not desirable at present without an adequate number of cases with sufficient length of follow-up, as it may lead to premature conclusions. Can one judge on the observation of 1 case of mucoid cancer in a series of 25 cases out of which only 2 had a five year follow-up period?

In an earlier article on "Mammary Cancer of Youth" (*Surg., Gynec. & Obst.* 77:55 [July] 1943) 73 cases of breast cancer under the age of 30 years were reviewed. The records of these patients were collected from six leading hospitals of New York and Boston, with follow-up periods over five and ten years. From this study it was learned that the previously held belief that the prognosis for women with breast cancer under 30 years of age is fatal is untenable. Results in such younger groups could be favorably compared to the general series (Eggers, Carl; de Cholnoky, Tibor, and Jessup, D. S. D.: *Ann. Surg.* 113:321 [March] 1941).

The five year survival was found to be 40.8 per cent and the ten year arrest 37 per cent in all cases in which operation was performed. Included in this series is a patient 23 years of age with bilateral breast cancer. She gave birth to a child five years after the first radical operation and a year after that had a radical operation for cancer of the other breast. This patient is well twelve years after the original operation.

In patients with small tumors less than 2 centimeters in diameter lymph node involvement was rarely found. Among these patients 10 out of 11 survived the five year period, although no oophorectomy or x-ray castration was performed.

Early diagnosis, therefore, is imperative when dealing with small solid tumors. Often this can be made only by a frozen section. In such cases oophorectomy may be omitted, even if further observations on a larger series with a longer follow-up period should indicate its beneficial influence.

Endocrine influence on tumor formations is a possibility, and it was also mentioned in one of our articles (*Arch. Surg.* 38:79 [Jan.] 1939). It is not exactly known as yet whether the elimination of ovarian function alone could reduce carcinogenesis or promote cancerous growth. At present it may be hasty to advocate oophorectomy in all cases of early breast cancer in the premenopausal stage. Clinical evidence with few recurrences points to satisfactory results following a carefully performed radical operation, after which no "small amount" of cancer cells should remain which could be stimulated by estrogenic substances. Additional mutilating operations therefore ought to be limited to more advanced cases with metastasis or recurrent lesions until further well controlled investigations confirm the beneficial effect of bilateral oophorectomy in breast cancer.

Finally I would like to point out the statement in the editorial that "mucoid cancer . . . probably arises from the stroma. . . ." This is obviously a mistake.

TIBOR DE CHOLNOKY, M.D., New York.

Council on Medical Education and Hospitals

GRADUATE CONTINUATION COURSES FOR PRACTICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals, advance information concerning graduate continuation courses for practicing physicians available in various centers is published semiannually. The following list

consists of courses beginning during the period June 30 through Dec. 31, 1944. It is hoped that this material will be useful to physicians seeking opportunities for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the proper executive officer.

Institutions offering continuation courses are invited to announce such courses in these semiannual lists compiled by the Council on Medical Education and Hospitals.

American Academy of Ophthalmology and Otolaryngology, Mayo Clinic, Rochester, Minnesota	Home Study Course in Ophthalmology	Continuously for 6 mo start Aug Sept 1, 1944	20

Graduate Continuation Courses for Practicing Physicians—June 30, 1944–Dec. 31, 1944—Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Surgery of the Eye ¹	Sept. 27-28, 1944, 2 days full time	\$4
	Motor Anomalies of the Eye ¹	Sept. 18 thr. 23, 1944, 6 days full time	60
	Anomalies of Ocular Muscles ¹	Sept. 25 thr. 30, 1944, 6 days full time	50
	Slit Lamp Diagnosis ¹	Oct. 2 thr. 6, 1944, 5 days part time	45
	Ophthalmic Neurology ¹	Oct. 2 thr. 6, 1944, 5 days, part time	45
	Embryology, Histology and Pathology of the Eye ¹	Oct. to Nov. 1944, 15 sessions, part time	75
Columbia University, At Mt. Sinai Hospital, 5th Avenue and 100th Street, New York 29, New York	Ophthalmic Surgery ¹	Sept. 27 thr. Dec. 13, 1944, 12 weeks	50
	Slit Lamp Microscopy ¹	Oct. 4 thr. Nov. 22, 1944, 8 weeks	20
	Refraction ¹	Oct. 5 thr. Dec. 21, 1944, 11 weeks	45
	Intra Ocular Muscles ¹	Oct. 6 thr. Nov. 25, 1944, 8 weeks	20
	Histopathology of the Eye ¹	Sept. 29 thr. Dec. 15, 1944, 12 weeks	50
	External Diseases of the Eye ¹	Oct. 5, 1944 thr. Jan. 25, 1945, 16 weeks	35
	Embryology of the Eye ¹	Oct. 3 thr. Nov. 21, 1944, 8 weeks	35
	Physiological Optics ¹	Oct. 4 thr. Nov. 8, 1944, 6 weeks	25
	Ophthalmological Neurology	Oct. 6 thr. Nov. 24, 1944, 8 weeks	25
	Ophthalmoscopy (Elementary)	Sept. 25 thr. Dec. 11, 1944, 12 weeks	20
	Plastic Surgery ¹	Arranged. 13 hours	75
	Operative Eye Surgery (cadaver) ¹	Arranged. 1 month	75
	Glaucoma Clinic ¹	Arranged. 10 hours	40
	Neuro Ophthalmology ¹	Arranged. 1 month	50
	Perimetry ¹	Arranged. 1 month	40
	Reading Disabilities ¹	Arranged. 2 weeks	30
	Orthoptics ¹	Arranged. 1 month	40
	Motor Anomalies and Orthoptics ¹	Arranged. 1 month	40
	Refraction ¹	Arranged. 3 months	100
	Slit Lamp Microscopy ¹	Arranged. 1 month	50
At: New York Eye and Ear Infirmary, 218 2d Avenue, New York 3, New York	Ophthalmoscopy ¹	Arranged. 1 month	40
	External Eye Diseases—Ocular Therapy ¹	Arranged. 1 month	40
	Bacteriology, Serology and Immunology ¹	Arranged. 1 month	40
	Histopathology ¹	Arranged. 3 months	85
	Embryology ¹	Arranged. 1 month	40
	Anatomy and Physiology ¹	Arranged. 1 month	40
	Contact Lenses, Telescopic Spectacles, Optics ¹	Arranged. 1 month, 2 months	1 mo. 40 2 mo. 75
	Refraction	Arranged. 6 weeks, part time	100 ^{3, 4}
	Ophthalmology (also cadaver)	Oct. 1, 1944, 3 months, part time	275 ^{3, 4}
	Ophthalmology	Oct. 1, 1944, 6 weeks, part time	100 ^{3, 4}
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19, New York	Ophthalmic Histology and Pathology	Oct. 1, 1944, 6 weeks, part time	60 ⁵
University of Pennsylvania Graduate School of Medicine, At: Wills Eye Hospital, 1691 Spring Garden, Philadelphia, Pennsylvania		Arranged. 8 weeks, 96 hours	200
Alumni Association of Medical College of State of South Carolina, Charleston, South Carolina	Ophthalmological and Otorhinological Continuation Course	Nov. 12, 1944, 2 days	None
Virginia Society of Otolaryngology and Ophthalmology, Box 1635, University Station, Charlottesville, Virginia	Ophthalmology (given in conjunction with 2 day course in Otolaryngology)	Approximately 2d week in Dec. 1944, 2 days	10
ORTHOPEDIC SURGERY (See Also Anatomy, Fractures)			
University of Minnesota, At University of Minnesota Center for Continuation Study, Minneapolis 14, Minnesota	Orthopedics	Announced. 3, 6 or 12 days	15, 25, 50
	Orthopedies in General Practice	Oct. 23 thr. 28, 1944, 6 days, full time	50
	Injuries to Bones and Joints	Oct. 2 thr. Nov. 23, 1944, 8 weeks	25
OTOLOGY			
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Surgical Anatomy as Applied to Otology ¹	Arranged. Part time	per hr. 10
	Histopathology of the Ear ¹	Oct. 3 thr. Nov. 9, 1944, 6 weeks	50
	Anatomy of Temporal Bone ¹	Arranged. 1 month	45
Columbia University, At Mt. Sinai Hospital, 5th Avenue and 100th Street, New York 29, New York	Clinical Otology ¹	Arranged. 1 month	40
Columbia University, At: New York Eye and Ear Infirmary, 218 2d Avenue, New York 3, New York	Otologic (Cadaver) Operations	Arranged. 2 weeks, 20 hours	100
University of Pennsylvania Graduate School of Medicine, At University of Pennsylvania Anatomical Laboratory, Philadelphia, Pennsylvania			
OTORHINOLARYNGOLOGY (See Also Anatomy, Endoscopy)			
University of Illinois College of Medicine, 1853 West Polk Street, Chicago 12, Illinois	Refresher Course of Otolaryngology for Specialists ¹	Sept. 25, 1944, 1 week	50
American Academy of Ophthalmology and Otolaryngology, Mayo Clinic, Rochester, Minnesota	Home Study Course in Otolaryngology	Sept. 1, 1944, continuously for 0 months	10
University of Minnesota, At: University of Minnesota Center for Continuation Study, Minneapolis 14, Minnesota	Otolaryngology	Announced. 3, 6 or 12 days	15, 25, 50
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Surgical Anatomy as Applied to Rhinology and Laryngology ¹	Arranged. Part time	per hr. 10
	Diagnostic Procedures	Oct. to Dec. 1944, arranged, part time	40 60
Columbia University, At: New York Eye and Ear Infirmary, 218 2d Avenue, New York 3, New York	Embryology, Histology and Pathology of Ear, Nose and Throat ¹	Oct. to Nov. 1944, 15 sessions, part time	75
	X-Ray ¹	Arranged. 6 hours	25
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19, New York	Operative Ear Surgery, Nasal Sinuses (Cadaver) ¹	Arranged. 1 month	110
	Otolaryngology (Eye, Ear, Nose and Throat)	Oct. 1, 1944, 6 weeks, full time	100 ³
	Otolaryngology (Ear, Nose and Throat)	Oct. 1, 1944, 6 weeks, part time	75 ³
Virginia Society of Otolaryngology and Ophthalmology, Box 1635, University Station, Charlottesville, Virginia	Otolaryngology (also Cadaver)	Oct. 1, 1944, 3 months, full time	600 ³
	Otolaryngology (given in conjunction with 2 day course in Ophthalmology)	Approximately 2d week in Dec. 1944, 2 days	10

Graduate Continuation Courses for Practicing Physicians—June 30, 1944–Dec. 31, 1944—Continued

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
PATHOLOGY			
Catholic University of America, Washington, D. C. At: St. Elizabeth's Hospital, Anacostia, D. C.	Brain Pathology	Oct. 4, 1944, approximately 3 months	\$150 seems 14 less than 7 hr., \$10 per seme. hr. Arranged
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19, New York	Practical Laboratory Instruction in Pathology and Bacteriology	Arranged	
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Gross and Microscopic Pathology	Sept. 15 thr. Oct. 30, 1944, approximately 6 weeks	50
	Surgical Pathology	Sept. 20, 1944 thr. Jan. 4, 1945, approximately 14 weeks	150
	Pathology of Blood and Blood Forming Organs	Nov. 1, thr. 30, 1944, 1 month, part time	75
	Pathological Physiology: Functional and Chemical Aspects	Oct. 9 thr. 13, 1944, 5 days, full time	45
PEDIATRICS			
(See Also Allergy, Cardiovascular Diseases, Endocrinology, Neurology and Psychiatry Obstetrics and Gynecology)			
Children's Memorial Hospital, 707 Fullerton Avenue, Chicago 14, Illinois	Postgraduate Course in Pediatrics	Oct. 2 thr. 28, 1944, 4 weeks	100
Kansas Medical Society, 112 West 6th Street, Topeka, Kansas At: 57 areas throughout Kansas	Pediatrics ^a	July 1944, 1½ days	5
Harvard Medical School Courses for Graduates, 25 Shattuck Street, Boston 15, Massachusetts At: Massachusetts General Hospital and Children's Hospital, Boston, Massachusetts	Pediatrics (A)	July 31 thr. Aug. 12, 1944, 2 weeks, daily	\$75 (\$50 extra for added 2 wk.)
University of Minnesota. At: University of Minnesota Center for Continuation Study, Minneapolis 14, Minnesota	Pediatrics	Announced. 3, 6 or 12 days	15, 25, 50
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Symposium on Recent Advances in Pediatrics	Oct. 16 thr. 21, 1944, 6 days, full time	50
Columbia University. At Mt. Sinai Hospital, 5th Avenue and 100th Street, New York 29, New York	Clinical Pediatrics	Oct. 3 thr. Nov. 23, 1944, 8 weeks	50
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19, New York	Pediatrics	Arranged. 4 weeks, part time	50 ^a
Southern Pediatric Seminar, Saluda, North Carolina	Southern Pediatric Seminar	July 17 thr. 20, 1944, 12 days	25
William Buchanan Foundation. At: Children's Hospital and University of Texas Medical Branch, Galveston, Texas	Pediatric Conference	Announced. 2 days	None
PHYSICAL THERAPY			
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Practical Instruction in Physical Therapy as Applied to Diseases of the Skin	Arranged. Part time, 6 weeks, 3 months	6 wk. 50 3 mo. 50
Columbia University. At: Mt. Sinai Hospital, 5th Avenue and 100th Street, New York 29, New York	Physical Therapy	Oct. 3 thr. Nov. 23, 1944, 8 weeks	50
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19, New York	General Course in Physical Therapy	Arranged. 4 weeks, part time	100 ^a
American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago 2, Illinois. At Statler Hotel, Cleveland, Ohio	Physical Therapy Lectures	Sept. 6, 7, 8, 1944, 3 days	\$2 single lec. \$15.9 lect.
POLIOMYELITIS			
Postgraduate School of Physical Therapy Warm Springs Found. At: Georgia Warm Springs Foundation, Warm Springs, Ga.	Treatment of Acute and Convalescent Poliomyelitis	First Monday of each month, 5 consecutive days	None
University of Minnesota. At: University of Minnesota Center for Continuation Study, Minneapolis 14, Minnesota	Kenny Technique for Management of Infantile Paralysis	Every other month, 6 days	25
PROCTOLOGY			
Tufts Medical School Postgraduate Division, 30 Bennett Street, Boston 11, Massachusetts	Proctology I Proctology II	Oct. 23 thr. 28, 1944, 6 days Nov. 6 thr. Dec. 1, 1944, 2 or 4 weeks	25 50 to 100
Long Island College of Medicine, Medical Society of County of Kings and Academy of Medicine, Brooklyn At: Jewish Hospital, 555 Prospect Street, Brooklyn, New York	Proctology	Oct. 16, 1944, twice weekly for 4 weeks	25
Columbia University, New York Postgraduate Medical School, 303 East 20th Street, New York 3, New York	Surgical Anatomy as Applied to Colon and Rectum	Arranged. Oct to Dec. 1944, 12 hours, part time	100.
Columbia University. At Mt. Sinai Hospital, 5th Avenue and 100th Street, New York 29, New York	Proctology for Surgeons (Advanced)	Oct. 4 thr. Nov. 24, 1944, 8 weeks	65
New York Polyclinic Medical School and Hospital, 345 West 50th Street, New York 19, New York	Medical Proctology Proctology Proctology (Cadaver)	Oct. 3 thr. Nov. 21, 1944, 8 weeks Oct. 1, 1944, 6 weeks, part time Oct. 1, 1944, 6 weeks, part time	25 75 ^a 200 ^a
PUBLIC HEALTH			
University of Michigan School of Public Health, Ann Arbor, Michigan	Public Health Economics Postwar Preparation for County and City Health Officers	Announced. 3 days to 2 weeks Announced. 3 days
University of Minnesota. At: University of Minnesota Center for Continuation Study, Minneapolis 14, Minnesota	Public Health	Announced. 3, 6 or 12 days	15, 25, 50
University of North Carolina School of Public Health, Chapel Hill, North Carolina	Public Health and Related Fields	Arranged. 1 quarter	100
RADIOLOGY			
(See Also Dermatology and Syphilology)			
American Roentgen Ray Society and Radiological Society of North America, 744 Jeffery Avenue, Chicago, Illinois At: Palmer House, Chicago, Illinois	Refresher Course Program	Sept. 24 thr. 29, 1944, 6 days	\$2 to \$7 ¹⁰
Harvard Medical School Courses for Graduates, 25 Shattuck Street, Boston 15, Massachusetts At: Boston City Hospital	General Roentgenology	Monthly except July, 1 month, mornings	50
University of Minnesota. At: University of Minnesota Center for Continuation Study, Minneapolis 14, Minnesota Columbia Hospital, East Gun Hill Road, Bronx, New York	General Roentgenology	Monthly. 1 month, daily	100
	Radiology	Announced. 3, 6 or 12 days	15, 25, 50
	Röntgenology of the Thorax	Oct. 19 thr. Dec. 7, 1944, 2 mo., 1 day per week	55
	X-Ray Diagnosis	Oct. 5, 1944, 10 Thursdays	70
Long Island College of Medicine, Medical Society of County of Kings and Academy of Medicine, Brooklyn At: Jewish Hospital, 555 Prospect, Brooklyn, New York	Radiology	Arranged. 2 months	120
New York Medical College, Flower and Fifth Avenue Hospitals, 1 East 10th Street, New York, New York	Diagnostic Roentgenology and Radiotherapy (Advanced)	First of any month, 6 weeks 3 months, full time	17 ¹⁰ 200 ¹⁰

VENEREAL DISEASE			
(See Also Dermatology & Syphilology)			
United States Public Health Service, Hot Springs National Park, Arkansas	Management and Control of Venereal Diseases	Announced 3 weeks	..
New York City Department of Health At Bureau of Social Hygiene, 125 Worth Street, New York, New York	Postgraduate Course in Venereal Disease ¹	Continuously, 10 weeks	None
Institute for Control of Syphilis, University of Pennsylvania Philadelphia 4, Pennsylvania	10 days' Intensive Training Course in Venereal Disease Control	Arranged 10 days	25
	3 wk Venereal Disease Review Course ¹⁸	Arranged 3 weeks	35
	6 mo Essential Basic Training Course ¹⁸	Arranged 6 months	125
	4 wk Intensive Review Course ¹⁸	Arranged 4 weeks	50

1 For specialists only

2 Women not admitted

3 Free or special fee to physicians in service

4 Grants may be made from scholarship fund

5 A few scholarships covering tuition for tuberculous physicians

6 For members of Kansas Medical Society and physicians in service

7 Dentists also are admitted

8 For certificate of attendance if physician has attended 3 of 4 meetings

9 Full time faculty members of Creighton and Nebraska University free

10 Varying with time of attendance

11 Laymen also admitted

12 For psychiatrists in training for practice of psychoanalysis

13 For staff members of mental institutions

14 For Negro physicians

15 For physicians who have had at least 2 years' special training in ophthalmology or 5 years' experience in same

16 Free to members of two societies, fellows, residents and interns in radiology

17 Licensed physicians in New York City

18 For public health officers etc

19 Illinois physicians free

20 For physicians who have had experience in electrocardiography.

Medical Examinations and Licensure**COMING EXAMINATIONS AND MEETINGS****EXAMINING BOARDS IN SPECIALTIES**

Examinations of the Examining Boards in Specialties were published in THE JOURNAL, July 1, page 674.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, Oct. 24-26. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, September 5. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

COLORADO * Denver, July 10-12. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT: * Written New Haven, July 11-12. *Endorsement.* New Haven, July 25. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homoeopathic* Derby, July 11-12. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, Oct. 10-12. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA * Washington, November. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

HAWAII: Honolulu, July 10-13. Sec., Dr. J. A. Morgan, 55 Young Bldg., Honolulu.

IDAHOO: Boise, July 11. Dir., Bureau of Occupational Licenses, Mrs. Lela D. Painter, 355 State Capitol Bldg., Boise.

INDIANA: Indianapolis, Jan. 3-5. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 301 State House, Indianapolis 4.

IOWA: * Iowa City, Sept. 25-27. Dir. Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Nov. 2-3. Sec., Board of Medical Registration and Examination, Dr. J. I. Hassig, 505 N. Seventh St., Kansas City.

KENTUCKY: Louisville, Sept. 11-12. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville.

LOUISIANA: September. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MASSACHUSETTS: Boston, July 11-14. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 F. State House, Boston.

MICHIGAN: * Ann Arbor, July 24-26. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 109 W. All-gan St., Lansing 8.

MINNESOTA: * Minneapolis, Aug. 29-31. Sec., Dr. J. T. Du Bois, 250 Lowry Medical Arts Bldg., St. Paul.

MISSOURI: St. Louis, Sept. 7-9. Sec., State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.

MONTANA: Helena, Oct. 2-4. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEBRASKA: * Omaha, Sept. 24-28. Dir., Bureau of Examining Boards, Mr. Oscar T. Humble, 1009 State Capitol Bldg., Lincoln.

NEVADA: Carson City, Aug. 7. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.

NEW MEXICO: * Santa Fe, Oct. 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH CAROLINA: Raleigh, Sept. 11-12. Sec., Dr. W. D. James, Hamlet.

OHIO: Examination Columbus, Sept. 26-29. *Endorsement* Columbus, Oct. 3. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, Sept. 16. Sec., Dr. J. D. Osborn, Jr., Frederick.

OREGON: * Portland, July 26-27. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Harrisburg, July 11-15. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 358 Education Bldg., Harrisburg.

SOUTH DAKOTA: Pierre, July 18-19. Dir., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Pierre.

VERMONT: Burlington, Sept. 12-14. Sec., Dr. F. J. Lawless, Richford.

VIRGINIA: Richmond, Sept. 19-22. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON: * Seattle, July 10-12. Dir., Department of Licenses, Mr. Thomas A. Swazze, Olympia.

* Basic Science Certificate required

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

DISTRICT OF COLUMBIA: Washington, October. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, Nov. 4. Final date for filing application is Oct. 20. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

IOWA: Des Moines, July 11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

RHODE ISLAND: Providence, Aug. 16. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Bureau of Legal Medicine and Legislation**MEDICOLEGAL ABSTRACTS**

Malpractice: Appendicitis Mistaken for Ptomaine Poisoning.—Donald Lawless, a 12 year old boy, on March 1, 1939 suffered abdominal pains with attendant vomiting and diarrhea. The following day he was taken to the physician defendant, who took the case history (which indicated that the boy had eaten moldy bologna the previous day), examined the boy's abdomen by palpation and percussion, took his temperature and examined his chest and lungs. The physician informed an aunt who accompanied the boy to his office that the boy probably had an attack of ptomaine poisoning but also stated "it sounds like we might have an attack of appendicitis." He recommended a diet, prescribed medicine for ptomaine poisoning and ordered the boy put to bed with an ice bag on the abdomen. On March 3 the physician was told that the patient seemed better. The next day, however, his condition seemed worse and he was removed to a hospital, where blood and urine analyses were taken. The hospital record dated on admittance contained the following entry labeled working diagnosis: "After physical examination, ptomaine, due to canned bologna—Possible appendicitis involved." The physician visited his patient daily or more often. On March 7 the physician's office associate, after consultation, made a diagnosis of appendicitis. The boy's condition grew much worse March 9 and the physician advised surgery. Dr. Morgan, a surgeon, was consulted and diagnosed the condition as "peritonitis, possibly due to appendicitis, retrocecal." The ensuing operation, at which the defendant assisted, disclosed a ruptured appendix and the boy died a few hours after the operation. The plaintiff, the mother of the boy, subsequently brought suit for malpractice against the physician defendant. At the conclusion of the plaintiff's evidence the trial court entered a judgment of nonsuit and the plaintiff eventually appealed to the Supreme Court of California.

The plaintiff contended first that the judgment of nonsuit was erroneous since sufficient evidence had been introduced at the trial to warrant a finding by the jury that the physician defendant had been negligent in his diagnosis and treatment of his patient. In passing on this contention the Supreme Court deemed it advisable to state the rules of law measuring a physician's liability for malpractice. The law demands, said the Supreme Court, only that a physician have the degree of the learning and skill ordinarily possessed by practitioners of the medical profession in the same locality and that he exercise ordinary care in applying such learning and skill in diagnosing his patient's ailments and in prescribing for and treating his patient. Ordinarily, a physician's failure to possess or exercise the requisite learning or skill can be established only by the testimony of experts. Where, however, negligence on the part of a physician is demonstrated by facts which can be evaluated by resort to common knowledge, expert testimony is not required since scientific enlightenment is not essential for the determination of an obvious fact. The plaintiff argued that the jury could have found that the physician was negligent on the theory that after the physician correctly diagnosed the ailment as appendicitis he failed to treat his patient therefore, but instead treated him for ptomaine poisoning. The evidence, answered the court, does not substantiate this premise. It clearly appears that although the physician at all times considered the possibility of appendicitis, he concluded, as a result of his examination, the presence of certain symptoms including diarrhea, and the history of the boy's having eaten

bologna, that his patient was suffering from ptomaine poisoning, and prescribed accordingly.

The plaintiff next argued that the jury could have found that the defendant was negligent in failing to diagnose positively the case as appendicitis at an earlier date than he did and that such a finding could have been based on expert testimony as well as the common knowledge of the jurors. No expert testimony, answered the court, was introduced to show that in light of the case history of the patient, the symptoms manifested, and the facts disclosed by the examination, the defendant was negligent in failing to diagnose the ailment as appendicitis at an earlier date. The only witnesses who appeared and could have qualified as experts were Dr. Morgan, the operating physician and the defendant himself. Dr. Morgan's testimony did not indicate or intimate that the defendant's diagnosis was not consistent with what other physicians in the community would have arrived at under similar circumstances in the exercise of reasonable care. He testified principally as to his own conduct or course of action at a time when the defendant had diagnosed the case as appendicitis. Furthermore, the fact that another physician might have elected to treat the case differently or use methods other than those employed by the defendant does not of itself establish negligence.

As indicating that there was sufficient evidence introduced to warrant a finding of negligence on the part of the defendant, the plaintiff argued that Dr. Morgan's testimony showed that the standard practice in the community required a blood count to be taken when appendicitis was suggested and that the defendant failed to take a blood count. The argument, said the court, however, does not find support in the record. In response to the question "In any case, Doctor, suggesting the presence of appendicitis, in the exercise of that standard of degree of care in this community, is a blood count indicated?" Dr. Morgan answered:

I cannot answer that yes or no; but I can answer it. Let me explain a few things. When we think of blood count as something which will indicate to us whether there is a pus condition somewhere or reaction to the system of an infection, it does not of itself indicate appendicitis. We take those counts just to verify our idea that there is an infection process in the system, but we do not depend upon it to say that we have appendicitis. I have tried to explain when we take counts and I will . . . also state a great majority of us do when some of us do not.

Dr. Morgan did not say that a blood count should be taken for the purpose of diagnosis in all cases of possible appendicitis. Moreover, as previously noted, the patient's blood count was taken on March 4, when he entered the hospital, and certainly there is no suggestion in Dr. Morgan's testimony that the exercise of ordinary care in this case required the taking of a blood count before March 4, in view of the facts disclosed by the examination.

We believe, continued the court, that expert testimony was necessary to enable the jury to determine the issues in this case. Medical learning was necessary to guide the mind of the unskilled jury in determining whether failure positively to diagnose the illness as appendicitis at an earlier date resulted from negligence on the part of the physician. The proper methods to be employed in the diagnosis of an internal abdominal ailment, as well as the merits of such a diagnosis, are peculiarly within the knowledge or province of experts. The plaintiff argued, however, that laymen are so familiar with the use of roentgenograms that the jurors would have been justified in drawing on their common knowledge as a basis for a finding that the defendant physician was negligent in failing to have roentgenograms taken. While it has been intimated, said the court, in some cases that the use of roentgenograms as an aid to careful diagnosis of traumatic injuries is a matter of common knowledge, we cannot say that the use of roentgenograms in the diagnosis of an internal abdominal ailment such as revealed by the facts in this case is so well established that the jury

could have determined, of its own knowledge, that failure to take roentgenograms constituted negligence. It was not only necessary for the plaintiff to prove a mistake in diagnosis, but also that the mistake was due to failure to exercise ordinary care in making the diagnosis, and mere proof that the treatment was unsuccessful is not sufficient to establish negligence. We are satisfied that there is no evidence in the record before us showing that the defendant physician was negligent in the diagnosis or treatment of his patient's ailment. It follows that the trial court could have properly granted a nonsuit.

At the trial the plaintiff called the physician defendant as a witness and propounded the following questions to him:

1. From what you saw there, Doctor, you would say that that condition [ruptured appendix] had persisted for at least three days?

2. Doctor, the normal leukocyte count in a boy 12 years of age is between eight and ten thousand?

3. Doctor, do you know what the normal leukocyte count in the blood stream of a boy about 12 years of age is?

The trial court sustained objections to these questions on the ground that they called for expert testimony and that an adverse party called as a witness under the applicable California statute cannot be examined as an expert. This action the Supreme Court regarded as error, making it necessary to reverse the judgment of nonsuit. The applicable California statute, said the court, enables a party to call his adversary as a witness and to elicit his testimony without making him his own witness. This statute is remedial in character and should be liberally construed in order to accomplish its purpose. Any relevant matter in issue in a case is within the scope of the examination of a witness called pursuant to the provisions of that statute. It is well settled that a plaintiff in a malpractice action can establish his case by the testimony of the defendant therein. It is equally well settled that expert testimony is ordinarily required to prove the material or relevant issues in an action for malpractice. Neither the letter nor the spirit of the statute suggests any reason why the defendant in such an action should not be examined with regard to the standard of skill and care ordinarily exercised by physicians in the community under like circumstances and with respect to whether his conduct conformed thereto, even though such examination calls for expert testimony.¹

The plaintiff failed, although it was incumbent on her, to establish by expert testimony the standard of skill and care ordinarily exercised by practitioners in the community under like circumstances and that the defendant physician's conduct in this instance was not consistent therewith. While it may be true that favorable answers to the questions propounded to the defendant when he was called as a witness by the plaintiff would not have supplied the deficiency in expert testimony in this case, the plaintiff was precluded, by virtue of the trial court's ruling, from continuing with the examination of the witness and developing further the line of inquiry which might have elicited the essential expert testimony necessary to prove her case. For this reason the judgment of nonsuit was reversed.—*Lawless v. Calaway*, 147 P. (2d) 604 (Calif., 1944).

Society Proceedings

COMING MEETINGS

National Medical Association, St. Louis, Aug. 14-17. Dr. John T. Given, 1108 Church St., Norfolk, Va., Secretary.

Utah State Medical Association, Salt Lake City, August 24-26. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Obstetrics and Gynecology, St. Louis

47:445-592 (April) 1944. Partial Index

- Effect of Interval Between Births on Maternal and Fetal Outlook. N. J. Eastman.—p. 445.
Biologic Characteristics of Normal Vagina. A. E. Rakoff, L. G. Feo and L. Goldstein.—p. 467.
*Acute Anterior Poliomyelitis During Pregnancy. H. M. Weaver and G. Steiner, with technical assistance of Helen Ammon and Norma Hastings.—p. 495.
Carcinoma of Cervix: End Results. C. A. Behney and J. Y. Howson.—p. 506.
Salmonella Infection in Gynecology. H. C. Falk and G. Bliniek.—p. 514.
Uterine Motility Associated with Posterior Positions of Occiput: Observations Made with Löhrand Tocograph. D. P. Murphy.—p. 521.
Voorhees Bag. H. A. Power and H. W. Erving.—p. 527.
Management of Climacteric with Ethinyl Estradiol. R. A. Lyon.—p. 532.
Routine Order of Examinations for Diagnosis of Sterility. W. W. Williams.—p. 537.
Breech Presentation in Elderly Primipara. J. W. Walsh and Katherine Kuder.—p. 541.
Granuloma Pyogenicum of Cervix. R. P. Morehead, W. E. Woodruff and W. C. Thomas.—p. 546.
Eclampsia, Cerebral Abscess and Hemorrhage. S. L. Israel and B. J. Alpers.—p. 551.
Erythroblastosis Fetalis in Identical Twins. N. G. Deny.—p. 554.

Poliomyelitis During Pregnancy.—Weaver and Steiner discuss the question of pregnancy as a factor in susceptibility of the mother to the disease; the question of transmissibility from mother to fetus, and the question of transmissibility of the disease to the offspring through the secretions of the mammary glands. Relatively few cases of poliomyelitis acquired during pregnancy have been reported, but this may be due to incomplete reporting rather than to rarity of occurrence. Of the reported cases the smallest number (17.1 per cent) occurred during the first trimester of pregnancy. Studies by the authors on pregnant cotton rats furnished some evidence that chorionic gonadotropin or some substance associated with the formation or metabolism of this hormone might play a role in increasing the resistance of the pregnant female during the first trimester of pregnancy to the virus of poliomyelitis. There was no evidence that infective quantities of the Armstrong-Lausung strain of the virus of poliomyelitis were transmitted from the mother to the nervous tissues of the fetus in utero or from the mother to the nervous tissues of her offspring through the secretions of the mammary glands.

Carcinoma of Cervix.—Behney and Howson review observations on 580 patients with carcinoma of the cervix uteri and compare them with results obtained in an earlier group of 437 patients. They surveyed altogether 1,007 women with cervical cancer who died in the radiologic service of the Philadelphia General Hospital since 1922. Women with stage 4 lesions treated with external irradiation of high voltage x-ray therapy alone lived longer than those treated with lightly filtered radium alone. The best results were secured in the group in which, after regression of the primary lesion had been brought about by preliminary high voltage x-ray therapy, the patients were subsequently treated with heavily filtered radon at a distance of 1 cm. Since this fact became apparent, it has become the policy to administer external high voltage x-ray therapy preliminary to the radon application in every case of carcinoma of the cervix. The longer duration of life of patients in the recent series who were treated with high voltage x-ray therapy regardless of the stage of the disease is attributed to the fact that these patients were given more adequate dosage than those of the earlier series. External high voltage roentgen therapy is always beneficial and safe for even the most advanced stages of the

disease. In many apparently advanced lesions preliminary x-ray therapy will result in sufficient regression of the lesion, so that radon may be applied subsequently. Heavily filtered radon applied at a distance of 1 centimeter results in better palliation than the highly filtered radon in contact application.

Primary Carcinoma of Liver. D. L. Wilbur, D. A. Wood and F. M. Willett.—p. 453.
Dissecting Aneurysm of Aorta in Young Individuals, Particularly in Association with Pregnancy, with Report of Case. M. A. Schnitzer and C. A. Bayer.—p. 486.
Raw Food Diet: Therapeutic Agent. A. A. Holbrook.—p. 512.

Congestive Heart Failure in Edema of Acute Glomerulonephritis.—LaDue studied 12 patients with acute glomerulonephritis complicated by peripheral edema. The patients were placed on a strict bed rest and given no medication except magnesium sulfate to control convulsions. Four patients were given a low protein, low salt diet, 4 a high protein, low salt diet and 4 the regular house diet. There was no restriction of fluids, but the intake and output were charted. Daily measurements of venous pressure, circulation time, blood pressure, weight and degree of pulmonary, liver or peripheral edema were recorded. Frequent teleroentgenograms and electrocardiograms were made. The urine was examined at least twice a week, and blood urea and phenolsulfonphthalein excretion tests were

done. Blood proteins and albumin globulin ratios were determined. With the severity of heart failure as a basis for classification, the patients fall into three groups. The patients of group 1 had no symptoms of congestive heart failure except edema, but careful study revealed cardiac dilatation and elevated venous pressure. Patients in group 2 had, in addition to edema and elevated venous pressure, moderate to pronounced dyspnea and orthopnea. Patients comprising group 3 had such severe signs and symptoms of congestive heart failure that the administration of digitalis was necessary. The earliest objective evidence of improvement of the heart failure in 7 of 8 patients not given digitalis was a fall in blood pressure; the return to normal of the venous pressure and the disappearance of edema occurred slightly later. There was a significant decrease in the diastolic heart volume of these patients after compensation had been established. The circulation time was normal or low in 11 of 12 patients studied, despite an elevation of the venous pressure. The pulmonic second sound was accentuated in 11 of 12 patients, suggesting the possibility of pulmonary hypertension.

Sodium Lactate for Prevention of Renal Complications from Sodium Sulfadiazine.—Gilligan and his associates show that the effectiveness of adjuvant alkali therapy in preventing renal complications from sulfadiazine is attributable to the fact that alkalization of the urine increases the solubility of sulfadiazine and its N-acetyl derivative. They review observations on approximately 100 patients to whom sodium lactate was administered while receiving sodium sulfadiazine parenterally as prophylactic therapy before and after gastric or intestinal resections for ulcer or carcinoma or in the treatment of abdominal abscess or peritonitis. They found that alkalization of the urine with sixth molar sodium lactate solution administered parenterally prevents crystalluria and renal complications consequent to crystalluria during therapy with the usual doses of parenterally administered sodium sulfadiazine. The initial dose of sodium lactate required to alkalinize the urine at the onset of therapy with sodium sulfadiazine depends on the degree of acidosis present and varies usually from 500 to 1,500 cc. of sixth molar sodium lactate solution in adults with normal kidney function. Thereafter, 1,100 cc. of sixth molar sodium lactate solution daily is usually sufficient to maintain the urine alkaline and to prevent crystalluria from the sulfadiazine. The plasma carbon dioxide content is not greatly affected by this dosage of lactate solution. No evidence of clinical alkalosis was observed. Caution must be exercised to prevent alkalosis when attempting to alkalinize the urine of patients with nephritis. Studies on the sulfadiazine concentrations of blood following intravenous injection of sodium sulfadiazine convinced the authors that it is advisable to administer the drug in the relatively low concentration of 0.5 per cent in sixth molar sodium lactate solution or certain other parenterally utilizable isotonic solutions rather than in 5 per cent solution in water. They suggest that parenteral sodium lactate therapy as prescribed here would similarly be of value in protecting against renal complications from parenteral administration of other sulfonamide drugs.

Androgens and Somatic Growth in Man.—Kenyon and his collaborators review data on precocious puberty in boys with interstitial cell tumors of the testis and describe the association of somatic growth with the more familiar aspects of androgen action. Testosterone propionate and chorionic gonadotropin induce retention of nitrogen, inorganic phosphorus, sulfate and potassium in amounts so large as to necessitate the assumption of increase in the mass of nongenital tissue. Methyltestosterone has similar properties at least in several respects. Sodium and chloride are also retained for a period with these agents. Calcium retention can be induced in certain subjects with testosterone propionate. Creatinuria may be reduced by testosterone propionate but is increased by methyltestosterone. Basal heat production in the eunuchoid may be increased by testosterone propionate and methyltestosterone. Growth in height and weight of the undergrown underdeveloped boy may be produced by chorionic gonadotropin, testosterone propionate or methyltestosterone. Maturation of bony structure occurs, but closure of the epiphyses is not readily induced and presumably requires prolonged and heavy dosage. The testis is conceived as exerting profound general anabolic effects and thus accelerating the somatic growth of the boy. It is possible that feminine androgens similarly influence the growth of the girl. Certain nongenital sites of new tissue deposit in man under the influence of the androgens seem strongly suggested. These are the skeleton and the skeletal musculature. The kidney and other organs may be affected. The anabolic effects of the testis do not appear to be exerted either through the anterior lobe of the pituitary body or through the adrenal cortex. The mature normal testis is not exerting this anabolic or somatotrophic influence to the fullest extent to which the organism can respond. Since age does not seriously limit the metabolic response to the androgens, unknown opposing forces must operate to achieve the nitrogen equilibrium characteristic of maturity.

Infection of Lymphoid Tissue of Pharynx and of Conjunctiva. H. Waldapfel.—p. 331.

Meningococcal Conjunctivitis.—Mangiaracine and Pollen describe 10 cases of acute suppurative conjunctivitis of meningococcal origin all of which occurred within a five month period. In none was there a history of exposure or general prodromal symptoms. The ages varied from 14 weeks to 15 years. Frank meningitis developed in 1, and meningococcal septicemia with abortive meningitis in another. Cultures of material from the eyes yielded type I meningococci in 4 other patients and type II meningococci in 2. In the first 2 patients the organism was not typed. Both eyes were involved in 6 patients and one eye only in 4. There was corneal involvement in 5 patients, superficial ulcers developing in 2 and corneal edema alone in 3. In none did a permanent residual ocular change follow therapy. Treatment consisted of local and oral chemotherapy in 5 instances. Four patients received only local chemotherapy and 1 irrigations with zinc sulfate alone. The oral chemotherapy was given only to patients with corneal involvement or systemic or meningeal symptoms. Neither the degree nor the course of the ocular infection seemed to be improved by the addition of oral administration of sulfadiazine, and the patient who received

zinc sulfate alone did as well as the rest. The average length of hospitalization (exclusive of the cases with meningeal involvement) was eight days, the ocular discharge subsiding in three to five days and the eyes becoming white and the process quiescent in seven days. The apparent recent increase in the incidence of cases of suppurative conjunctivitis of meningococcus origin, previously considered of infrequent occurrence, leads one to believe that previous cases may have been missed because of the morphologic resemblance of the organisms to those in the neisserian group. Differential cultures will easily lead to the correct diagnosis, a factor of great importance when one is dealing with an organism of such potential epidemic virulence as the meningococcus.

Histopathologic Observations in Ménière's Disease.—Since the discovery by Hallpike and Cairns of a labyrinthine dropsy in the affected ear of 2 patients with Ménière's disease there have appeared a number of similar microscopic observations. Lindsay reports clinical and microscopic observations in a proved case of Ménière's disease. A man aged 47 fell during an attack of vertigo, suffered a fracture of the skull and died. In 1939 he had been examined at the Mayo Clinic and was considered as having Ménière's disease. The microscopic studies of the cochlea in this case corresponded closely to those in other cases. The hearing loss for low tones in the affected ear must have been associated with the hydrops of the labyrinth. Such a loss for low tones has been recognized as a primary characteristic of Ménière's disease. The deafness of Ménière's disease has been usually described as of nerve type because of the positive Rinne test. The primary low tone involvement and the fluctuations in threshold do not seem compatible with a neural lesion. The clinical features of deafness appear more compatible with some interference in the conduction medium in the inner ear. The histologic picture in this as well as in the 2 ears reported earlier by the author seems to lend support to this explanation of auditory disturbances in that the neural elements appeared well preserved in contrast to the great distortion of the membranous structures. In place of the normal column of perilymph from the oval window to the round window, the column had been broken up or distorted by the dilated saccule and cochlear duct at the expense of the perilymphatic cistern and vestibular scala. Such an architectural rearrangement seems a probable basis for a disturbance in the function of the fluid column. The dilatation of the saccule has been a fairly constant feature. The saccule has herniated into the small end of the horizontal semicircular canal in some, and in others there has been herniation of the utricle. In this case, as in the 2 cases formerly reported by the author, there has been a consistent tendency for herniation to develop from the utricle adjacent to the ampullae of the semicircular canals with distortion of the outer wall of the ampullae. This distortion of the ampullary wall offers a reasonable explanation for the disturbances of vestibular function. Permanent distortion of the ampulla would explain impairment of the vestibular response in late stages, while temporary distortion would result in an attack of vertigo and possibly also a temporary decrease in caloric response.

Tonsillectomy and Poliomyelitis.—Page presents figures on poliomyelitis for the years from 1937 to 1941 inclusive obtained from the Department of Health of the City of New York. An increase in the number of cases every other year was evident. As 1937, 1939 and 1941 were the years in which the disease was most prevalent, the patients who had tonsillectomies performed on them during those years were communicated with by mail; 27,849 cards were sent out by the Manhattan Eye, Ear and Throat Hospital. A total of 8,915 replies were obtained with only 1 instance of poliomyelitis, which occurred in August 1937, approximately a month after tonsillectomy. Six replies for the year 1937 reported illness other than poliomyelitis. Two replies for 1939 reported illnesses other than poliomyelitis. The data in 7 replies that reported illness after tonsillectomy all mentioned some spinal involvement.

*Treatment of Creeping Eruption with Fuadin. J. F. Wilson.—p. 425. Role of Fluids Administered Orally in Causing Postoperative Distention Following Cesarean Section and Gynecologic Operations: Report of 100 Cases. B. F. Hart.—p. 426.

Fuadin in Creeping Eruption.—Wilson restricts the term creeping eruption to the type caused by *Ancylostoma braziliense*, the larva of hookworm. The peak of the season for this larva migrans is in August. It is more prevalent along the coastal regions of the Gulf of Mexico and the South Atlantic than in other parts of the country. Most treatments hitherto recommended have been unsatisfactory. Freezing with ethyl chloride, one of the most effective methods, involves great expense. Smith's report in THE JOURNAL of Nov. 13, 1943, page 694, on the systemic treatment of the disease with fuadin, induced Wilson to employ it. He administered fuadin in 7 cases. In the first case five injections were given at daily intervals. Since no itching was felt after the first dose he decided to give only one injection in the subsequent cases. In 2 cases a second injection was required. The possibility of antimony poisoning is practically eliminated if 1 or 2 doses will suffice. Fuadin appears to be worthy of trial in the treatment of larva migrans.

Pregnant Mare Serum for Acne Vulgaris.—Birnberg and Rein report studies on pregnant mare serum from which they precipitate a hormone which is practically protein free. The material was studied on guinea pigs. The preparation was first given to patients intramuscularly. Since no effects resulted, intravenous injection was tried. The dosage varied from 400 to 800 international units intravenously twice a week. More than 5,000 injections have been given without a single reaction. The authors report results for a study of 17 female patients with acne vulgaris and associated menstrual disturbance who had received the usual treatment, including roentgen and ultra-violet irradiations, various types of vaccine injections, vitamin therapy, strict dietary limitations and various forms of local medication with slight or only temporary clinical improvement. Examination revealed negative follicle stimulating hormone and negative estrogens in 12 of the 17 patients. After treatment with the pregnant mare serum preparation no change occurred in 2 patients and normal values were found in 10 patients. Five patients failed to return for a recheck. Fourteen of the 17 patients were definitely improved by injections of pregnant mare serum. The administration of estrogen alone aggravated the eruption. The authors do not imply that pregnant mare serum is a cure for acne vulgaris. Certain cases respond to different types of endocrine therapy. Acne in a female which is influenced by the menstrual cycle should have a thorough endocrine study to determine the primary difficulty, and the condition should be treated accordingly.

Hyperinsulinism in Acute Rheumatic Fever.—Abrahamson calls attention to the fact that diabetes (hypoinsulinism) and rheumatic fever rarely coexist. He cites evidence that allergic disorders are characterized by hyperinsulinism. Since rheumatic fever is a variety of bacterial allergy, it was postulated that rheumatic subjects should also have hyperinsulinism. Dextrose tolerance tests of 11 patients having rheumatic fever disclosed that such was the case. The patients were placed on frequent feeding with a high fat and low carbohydrate diet. Sweets and other rich carbohydrate foods and caffeine beverages were forbidden. The patients were instructed to follow the diet closely for three months. They were permitted gradually to drop the extra feedings. By the end of six months they were on the usual three meals a day schedule. They continued to avoid caffeine and sweets and they kept the consumption of potatoes and other carbohydrate rich foods to a minimum. After these six months the patients were tested again. The diet had the anticipated effect of eliminating the hyperinsulinism. All of these patients went through two winters without further rheumatic attacks.

Rh Antibodies in Maternal Circulation Without Erythroblastosis in Child.—Dockeraay and Sachs point out that with regard to the homozygous and heterozygous genotype of Rh positive individuals, as suggested by Landsteiner and Wiener

in 1941, the probability of erythroblastosis would amount to about 9 per cent. Erythroblastosis probably occurs much less frequently than this figure. It follows that when the mother is Rh negative and the fetus is Rh positive certain conditions must be fulfilled for the disease to develop. The fetal red cells must pass the placental barrier, the mother's body must be able to react with antibody formation and the anti Rh isoantibodies must pass the placental barrier to cause erythroblastosis in the fetus. The authors examined serums of pregnant women before delivery for Rh antibodies. They detected irregular agglutinins in 3 of 61 antepartum cases. A fourth case was reported previously. In their observations mothers whose serum contained great amounts of anti Rh agglutinins did not give birth to infants exhibiting clinically demonstrable erythroblastosis. It follows that Rh antibodies may be found in the mother without erythroblastosis occurring in the child. The baby need not be erythroblastic even when all conditions seem to be fulfilled, that is an Rh negative mother bearing an Rh positive fetus with a strong formation of Rh antibodies in the mother. Since all 4 women were Rh negative, it is justifiable to draw the same conclusion from the other observations. Isoimmunization of the mother from the fetus in utero is apparently not always sufficient in itself to cause erythroblastosis. Perhaps the isoantibodies may pass the placental barrier only in certain conditions changing in the course of pregnancy. Since the passage of fetal red cells necessary for the antibody formation must be more difficult than that of antibodies, it appears likely that particular conditions or temporary damage in the placental barrier may be responsible for the transmission of antibodies from the mother to the fetus or for their action on the fetal red cells. The authors also observed 3 instances of erythroblastosis in infants whose mothers' blood contained at most only traces of anti Rh agglutinins.

Physiologic Basis of Concussion.—According to Walker and his associates, cerebral concussion is generally agreed to be a traumatically induced derangement of the nervous system characterized by temporary impairment of consciousness, dizziness, mild confusion and headache, and unassociated with gross anatomic changes. Since Duret's experimental study, technical procedures for precise measurement of intracranial changes have been developed and some understanding of neural mechanisms has been acquired, so that now the phenomena of concussion may be placed on a sound physiologic basis. The authors made studies on 151 cats, 15 dogs and 21 monkeys. Analysis of the clinical manifestations in these animals show that they are the result of intense excitation of the central nervous system at the moment of the blow to the head. At the moment of concussion an electrical discharge occurs within the central nervous system. In the vinethene-procaine anesthetized animal the cortical activity is increased in frequency following the initial discharge (after discharge) for ten to twenty seconds and then decreases until there is little spontaneous activity (extinction). Within several minutes the electroencephalogram becomes practically normal again. At the moment of a blow on the skull a sudden increase in pressure at the site of impact occurs with pressure waves being transmitted throughout the intracranial cavity. It is concluded that these mechanical forces produce a breakdown of the polarized cell membranes of many neurons in the central nervous system, thus discharging their axons. This

intense traumatic excitation is followed by the same electroencephalographic, chemical and clinical phenomena which characterize intense stimulation of the nervous system by electrical, chemical or other agents.

Removal of Protruded Intervertebral Disks.—Shinners and Hamby investigated the symptomatic relief obtained by 140 patients who underwent removal of protruded intervertebral disks. The shortest period following operation was six months. One hundred and sixty operations were performed on 140 patients. There were no fatalities. At the first operation 116 patients were found to have protruded disks. Eight patients had recurrences subsequently at the same level. Three patients had second disk protrusions at a new level. Twenty-four patients underwent exploration without discovery of disk protrusions. The first 9 patients were subjected to more or less complete laminectomy. Thereafter hemilaminectomy was employed. The interlaminar approach has been principally employed. Spinal fusion was done at the initial operation only if the back was frankly unstable. Otherwise it was done only when the simpler operation proved ineffective. Fusion was performed on 13 of the 116 patients from whom disk protrusions were removed and on 5 of 24 patients who on exploration proved to be without protrusions. Spinograms were made of 91 patients. The results of these were not only confusing but often misleading. Of the 87 patients who replied to follow-up questionnaires, 49 considered themselves cured, 48 believed they were improved and 2 thought they were worse. A comparison of the results in private and compensation cases showed a striking parallel.

Treatment of Phantom Limb by Removal of Postcentral Cortex.—The patients seen by de Gutiérrez-Mahoney felt pain in every phantom, but few were disabled by it. The unpleasant sensations included undue warmth, itching or simply distress due to overconsciousness of the painless phantom. These discomforts may be intermittent but are usually continuous. Many patients suffer a deep, agonizing torture due to the sensation of the limb being tightly compressed, which may be so severe that the victims are willing to undergo any kind of treatment. Many ultimately become morphine addicts. A man who had caught his right hand in a circular saw, which amputated the terminal phalanx of the middle finger and the terminal and half of the middle phalanx of the ring finger, was conscious of the presence of the amputated fingers. These phantoms were extremely painful, felt raw, itched and ached. The fingers become powerfully flexed and the pain was "killing." On Aug. 15, 1940 he suddenly became unconscious and partially paralyzed on the right side. He recovered considerable function of the limbs, and there was little if any sensory deficit. There was no alteration of the phantom fingers or pain. He had a few convulsions, after each of which the pain in the phantom disappeared for a day but later recurred. At an operation the left postcentral cortex was stimulated and the area corresponding to the middle and ring fingers for the right hand was determined and excised by subpial resection. There was an immediate disappearance of the phantom fingers and the pain. There had been no recurrence two years after the operation.

Thoracoplasty and Contralateral Pneumothorax in Bilateral Pulmonary Tuberculosis.—Buxton and O'Rourke show that in a certain group of tuberculous patients bilateral pneumothorax, although highly desirable, is technically impossible. These patients often are either denied collapse therapy or are treated only unilaterally. Thoracoplasty for the otherwise untreated lesion, in conjunction with a contralateral pneumothorax, is usually considered unwise for technical reasons and

valueless because of the final results. This study has been undertaken to determine the desirability of thoracoplasty in the presence of a contralateral pneumothorax and to analyze the immediate and late results of this form of combined therapy. The series is composed of 44 unselected consecutive patients having a unilateral pneumothorax, on whom 174 thoracoplasty stages have been performed for the lesions in the lung opposite to the pneumothorax. All patients had positive sputum on smear or concentrate examination at the time thoracoplasty was begun. In general the thoracoplasty was delayed until the lesions beneath the contralateral pneumothorax gave satisfactory evidence of progressive improvement. In 25 out of 30 patients there was regression of the lesions with closure of existing cavities on the side of the pneumothorax. In the other 5 the cavities were smaller and the progress of the disease indicated probable eventual closure. Serial roentgenograms showed the disease to be stationary on the pneumothorax side in 14 cases at the time the thoracoplasty was begun. Fifteen, or 34 per cent, of the 44 patients had some degree of tuberculous laryngitis or bronchitis. Only the larynx of 3 patients was involved and only the bronchi of 12 were involved. In 13 cases the planned thoracoplasty program was not completed because of complications. The early mortality rate (within three months) in this series was 6.8 per cent, and the late mortality rate was 22.7 per cent. The total mortality rate was 29.5 per cent. All living patients have been followed for more than one year since the last stage of their primary thoracoplasty. Among the 31 living patients (17 in sanatoriums and 14 at home) there has been conversion of sputum in 64.5 per cent and closure of the cavity under the thoracoplasty in 83.8 per cent. Twelve of the 14 patients at home are capable of pursuing a gainful occupation. The authors conclude that the performance of thoracoplasty in the presence of a contralateral pneumothorax is desirable and the results justify its more frequent employment in the treatment of bilateral pulmonary tuberculosis.

Intrathoracic Neurogenic Tumors.—Kent and his co-workers present the histories of 18 patients with intrathoracic nerve tumors treated at the Barnes Hospital in St. Louis and report 3 other cases of probably but not proved neurogenic tumors. A collected series of 105 cases from the literature is reviewed. A high percentage of the tumors were malignant. Of the 18 patients treated by the authors 7 had malignant tumors, and of the 105 cases collected from the literature 37 per cent were malignant. There is therefore no justification for the all too common opinion that suspected nerve tumors of the thorax do not require operation unless or until pressure effects have been noted. It would seem wiser to take the position that the presumptive diagnosis of such a tumor constitutes an indication for operation. Since the majority of the tumors are in the posterior mediastinum, a posterior operative approach is used most frequently. If the patient has an hourglass tumor it is preferable to remove both the intraspinal and the intrathoracic parts at the same operation. If such extensive surgery should be contraindicated at one stage, the intraspinal portion should be the point of attack.

Heart Failure in Aged.—According to Howell, heart failure in old age differs in many ways from that in earlier life. Before middle age the pathologic state of the heart itself is all important; after this the condition of the peripheral vessels also must be taken into account. In the young, recovery is more rapid and lasting; in the old, relapses are the rule. Howell analyzes cardiac failure in 75 old or elderly persons. The ages of the patients ranged from 62 to 92. No congenital or rheumatic heart disease was found, and only 1 patient had syphilitic heart disease. The most common causes of cardiac failure were high blood pressure, disease of the coronary artery and myocardial toxemia. Other varieties peculiar to senility seem to result from the inability of the left ventricle to propel the blood against the increased resistance of the thickened and narrowed peripheral arteries. They appear as peripheral ischemia, which may be intermittent or constant. It has been referred to as relative hypotension. The dominant symptoms are usually cerebral in origin. One symptom complex of this type has been described by the author under the name of progressive cerebral ischemia. Here an arteriosclerotic patient with high blood pressure shows first mental confusion, then restlessness or violence, and finally becomes comatose while his systolic figure falls from its previous high grade to the ultimate level (around 100 mm.), at which death ensues in such cases. This syndrome may follow right or left heart failure or may result from myocardial toxemia after an infection, such as pneumonia. Another form is designated as "forward" failure. This is the gradual but steadily increasing feebleness, accompanied by a slowly falling blood pressure. There is no angina pectoris, no congestive failure, no paroxysmal dyspnea, nor are cerebral symptoms prominent. The author stresses the frequency of multiple etiology in heart failure of the aged. He thinks that arterial thickening probably played a part in most of the cases, usually in association with hypertension or disease of the coronary artery. Sometimes myocardial toxemia was superadded, and this made a fatal prognosis almost inevitable.

Circulatory Failure Due to Vitamin B Deficiency.—Schott describes 3 cases of circulatory disturbances due to vitamin B₁ deficiency with special reference to some unusual clinical and electrocardiographic features. Two of the 3 patients took an excessive amount of alcohol; in the third case the condition was caused by deficient diet only. All responded to treatment with vitamin B₁.

Neostigmine and Ephedrine in Myasthenia Gravis.—Wilson and Stoner studied the clinical response to neostigmine, to ephedrine hydrochloride and to neostigmine with ephedrine in myasthenia gravis. The effect of this therapy on the cholinesterase activity of serum was determined in 10 patients with myasthenia gravis. The results obtained provide little if any evidence of relationship between the inhibition of serum cholinesterase and the clinical effect of neostigmine. Recent work on the nature of myasthenia gravis indicates that the essential lesion is a partial block in neuromuscular transmission. Neostigmine has been shown to have two types of action. It inhibits cholinesterase activity and is also capable of reversing the block in neuromuscular transmission produced by curare and some quaternary ammonium salts. Such a dual action might explain the failure to correlate the clinical effects with the inhibition of serum cholinesterase activity, for the anticompariform action of neostigmine is possibly independent of the inhibition of cholinesterase activity. The action of neostigmine with ephedrine is much greater than that of neostigmine alone. The principal effect of adding ephedrine was relief of diplopia. Where diplopia was not relieved by neostigmine alone it was alleviated during the combined therapy. The effect on asthenia was definitely superior to that of neostigmine alone; the patients volunteered this information without being questioned. In some of the cases ergographic records provided confirmation. As far as duration of the effect was concerned, the increase was between three and four hours. One of the patients, who required 2.5 mg. of neostigmine every hour, was maintained on combined therapy by injection every four hours. Administration of ephedrine by itself produced clinical improvement in only 1 case. In none did it alter the cholinesterase activity of the serum.

Ocular Signs of Riboflavin Deficiency.—Sydenstricker and his associates described in 1940 ocular signs and symptoms which responded to riboflavin therapy. The symptoms were photophobia, sensations of burning or roughness of the eyelids, visual fatigue and sometimes impairment of visual acuity in the absence of refractive errors or pathologic changes in the media. The commonest sign was "circumcorneal injection," often with invasion of the cornea by capillaries from the limbic plexus. Ferguson examined groups of people with the slit lamp and discussed and examined cases with Sydenstricker. He feels that misinterpretation has arisen largely through lack of experience in the use of the slit lamp, through imperfect understanding of the normal variations of the appearance and vascularity of the limbus and through inclusion of corneal vascularization due to other causes than riboflavin deficiency. The mode of anastomosis of the anterior and posterior conjunctival vessels around a normal limbus varies. There are four typical varieties, which demonstrate that formation of capillary loops at the corneal-scleral junction and on the limbus itself can be regarded as normal. The vascularization attributed to lack of riboflavin is an extension of the normal limbic vascular system to the true cornea. From the apexes of the existing limbic loops appear fine vessels running more or less toward the true cornea; these "streamers" in turn anastomose with one another to form further loops, from which further streamers and, in turn, loops may be formed. The true cornea may thus become further and further vascularized. These vessels run superficially, immediately under the epithelium, and are of such small caliber that they are

mostly invisible even with an ordinary binocular loupe. With the corneal microscope and slit lamp they show best when observed by light reflected from the iris, and they may readily be missed by direct corneal illumination. Abnormal corneal vascularization with very mild symptoms was found in 7.8 per cent of 422 persons. In 13 cases in which the effect of riboflavin treatment was studied over an adequate period it resulted in cessation of the abnormal corneal circulation. No claim is made that riboflavin deficiency is the only cause of the corneal condition described.

Diagnostic Value of Mester Reaction in Rheumatic Fever in Children: Modified Technic. J. Giampietro and V. H. Vacarezza.—p. 27.

Pulmonary Tuberculosis in Infant.—The case reported by Cantonnet and his collaborators of pulmonary tuberculosis with cavitation in an infant 6 months old controlled by phrenicectomy is the second in the literature. The infant's parents were normal. She had not BCG vaccination, was artificially fed and was in close contact with a tuberculous neighbor. At the age of 4 months she was hospitalized for an acute digestive disorder. The clinical symptoms and physical examination revealed pulmonary tuberculosis. The tuberculin test was positive. Roentgen examination of the thorax showed lymph node and lung tuberculosis. A pulmonary cavity was demonstrated in a roentgenogram at 6 months. Tubercle bacilli were found in the gastric lavage. Phrenicectomy was well tolerated. On a proper dietetic and hygienic regimen the patient gained weight and improved. Repeated examination for bacilli and inoculations of guinea pigs gave negative results. The roentgenograms of the chest showed closure of the pulmonary cavity and limitation of the tuberculous process.

Medical Extrapleural Serothorax and Pneumothorax: Technic. P. Rubinstein.—p. 2489.

Cirsoid Aneurysm of Wrist and Hand.—Bertola's patient, a girl aged 12 years, presented a tumor mass on the anterior aspect of the wrist and the palm of the hand. This was noted when she was an infant. The tumor became blue and painful as the patient grew. The motility, sensibility and function of the wrist, hand and fingers were normal. There was no pulsation nor aneurysmal bruit. The swelling was irregular and soft on palpation. The operation consisted in ligation of the artery and the vein and of total removal of the tumor. Abnormal communications between venules and arterioles were observed in several areas of the tumor. The clinical diagnosis of cirsoid aneurysm was verified by the microscopic study.

*Basal Metabolism and Specific Dynamic Action in Nutritional Edema. M. Carmena and E. Gómez Marcano.—p. 305.
Atypical Generalized Amiloidosis. Miranda Rodrigues and Pulido Valente.—p. 310.

Nutritional Edema.—Carmena and Gómez Marcano studied alterations of basal metabolism and of the specific dynamic action of proteins in 20 cases of nutritional edema. The basal metabolism was lower than normal, decreasing as low as 40 per cent in some cases. There was no correlation between the degree of lowering of the basal metabolism or of the plasma protein level and the severity of edema or of other manifestations of hyponutrition such as diarrhea, bradycardia, arterial hypotension and anemia. The basal rate persisted low for several months after the disappearance of symptoms, but in a number of cases in which it was determined two years after the clinical recovery this value was within the normal range. The decrease in basal metabolism is considered to be a defensive

reaction of the organism when subjected to a low caloric and protein intake and to be accomplished through the reduction of the thyroid activity. The specific dynamic action of proteins measured in 3 cases was found to be low in 1 and low normal in 2. After recovery this value rose to normal or high normal in all cases.

Gastric Sarcoma.—Forssman states that the incidence of gastric sarcoma is given variably as between 0.3 and 8 per cent of gastric malignant neoplasms. It may occur at any age but is most frequent between the ages of 40 and 60. The author reports clinical histories of 9 cases of gastric sarcoma that were treated at the "Radiumhemmet" in Stockholm. In all of these cases operation had been performed because a gastric tumor was diagnosed and carcinoma was suspected. Gross or microscopic examination established the sarcomatous nature of the lesion. In 6 cases a gastric resection was done, whereas in the 3 others only an exploratory excision was made because the neoplasm had advanced to the inoperable stage. The gastric resection was followed by postoperative roentgen treatment with daily doses of 250, 300 or 400 roentgens with a 0.5 mm. of copper or tin filter, 50 to 60 cm. focal distance and a total cutaneous dose of 2,500 to 3,000 roentgens during four to six weeks on each of two anterior and two posterior fields. Supplementary series were given two to three months later in some cases. In a case of inoperable reticular cell sarcoma a total dose of 5,250 roentgens in two series led rapidly to freedom from symptoms and complete restoration of working capacity. Many cases of sarcoma are often wrongly diagnosed as inoperable cancer on the basis of exploratory laparotomy and thus are not benefited by the radiotherapeutic possibilities. Biopsy should always be done in cases of inoperable tumors. The difference in localization between these and other gastric tumors is of importance in the roentgenologic differential diagnosis. The growth of the tumor in the submucosa and the fact that the mucosa long remains intact give rise to the typical bulging outline of the mucosa and to the early disturbances in peristalsis due to infiltration of the muscularis. The sarcoma frequently has a smooth surface, but occasionally there is a central crater.

Histologic Picture of Breast Cancer After Preoperative Irradiation.—Roentgen therapy of cancer has passed through several stages. The earliest massive single dose was abandoned in favor of fractionated postoperative irradiation, but this in turn has to some extent been superseded by the preoperative fractionated method. Hoffmeyer describes the microscopic appearance of breast cancer in 50 patients who had been treated preoperatively with fractionated doses of from 1,000 to 4,800 roentgens and subsequently were operated on. The patients were observed in Copenhagen hospitals between 1935 and 1940. Palpation revealed that in 40 cases the tumor had diminished in size; in 2 cases it had disappeared entirely. Microscopy revealed that the irradiation had resulted in a diminution of the cancer cell area more or less corresponding to the macroscopically observed recession of the tumor, but in no case was there complete disappearance of the cancer cells. In many cases the latter showed distinct degenerative changes. In 3 cases to such an extent that roentgen sterilization was likely. In most of the cases cancer cells of the pleomorphic type described by Halley and Melnick were found. It seemed as if a total radiation dose of 4,000 roentgens was slightly more effective than a dose of 2,000 roentgens. An observation made by the author himself, coupled with evidence from the literature, causes him to warn against too long postponement of the surgical operation, owing to the risk of fresh proliferation of the cancer cells.

Book Notices

Psychiatry in War. By Emilio Mira, M.D. Cloth. Price, \$2.75. Pp 206, with 6 illustrations. New York: W. W. Norton & Company, Inc., 1943.

This book is well written, brief and practical.

Dr. Mira has collected and analyzed his material carefully and has tested and recast his clinical and academic psychiatry in the light of actual experience of war both at the home front and in some of the bitterest fighting in any war. Thus tested, his formulations are not mere theory but expressions of psychiatrically sound, proved, clinical facts in the Spanish war.

His discussion of fear, anger, morale, management and direction of aggression are all clearly written. His points on recovery and readjustment should be inculcated in all militarized individuals: "Once a man has been enrolled and trained as a soldier, all efforts should be made to keep him in the army in the event that he becomes ill or injured. In other words, even if there are sufficient new recruits, it is always preferable to restore a veteran rather than to replace him by a novice." He discusses civilian morale factors and correctly brings out that civil and military personnel must not only know whom they are fighting but what they are fighting for and must be in the frame of mind to make war, not merely to support it.

All available manpower was employed in the Spanish war. The epileptic were retained and used where they could function adequately. The neurotic were not discharged unless they were so ill as to need commitment to an institution. The greatest of attention was paid to classification for men, assigning and reassigning them till in the optimal job for them and the army.

Some methods of therapy seemed a bit archaic, particularly the counterirritant therapeutic procedures in toxic states and the painful stimulation of the neurotic. However, the conditions under which he worked and the urgency to get men quickly rehabilitated may justify his use of these procedures, though unacceptable to us. The book is written simply and brings into sharp focus the need for proper guiding of attitude in morale of men and officers. It is recommended to all medical officers as a concise presentation of psychiatry in war.

Sheltered Care and Home Services for Public Assistance Recipients, with a Note on Methods of Conducting Studies of Public Assistance Administration. Federal Security Agency, Social Security Board, Public Assistance Report No. 3. Paper. Price, 25 cents. Pp 149. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

This study was confined to public assistance agencies in six urban localities in five states: Orleans Parish, La.; Baltimore, Md.; Cook County, Ill.; Jackson County, Mo., and Boston and Worcester, Mass. For the areas covered it is very thorough. It contains valuable information for welfare workers.

The study grew out of the concern of the bureau about the problems of state and local agencies in assisting aged and blind persons to obtain appropriate living arrangements. It was in line with the suggestion of the President's Committee on Economic Security that a federal agency undertake a survey of institutions for the care of the aged "with a view to recommending a constructive program for the improvement of institutional maintenance of the aged."

The report is divided into four principal phases. Under I, on private sheltered care, it is stated that the proportion of the aged in the general population is increasing and the incidence of chronic illness among the aged is high; also that many more recipients are living in sheltered arrangements than are known. The right of the recipient to use his money payment in bargaining for goods and services should be recognized and protected. The public assistance agency should stimulate community planning to establish standards of care and should participate in efforts to maintain these standards. In II, on sheltered care and public institutions, some significant findings are set down. "The time may be at hand when the public home, like other public institutions, should be regarded as an essential and permanent public service. . . . The scope of the study does not permit the forthright conclusion that the federal government should take steps to participate either in a grant-in-aid program to public institutions or in matching of assistance payments to

inmates of public institutions. . . . Within the present legal framework of federal, state and local public assistance agencies, current interpretations of the use of public institutions by recipients of old age assistance and aid to the blind can be liberalized so that any type of public institution, including the public home, can be considered as a resource for temporary shelter and care of recipients." Services in recipients' homes and guardianship of adult recipients are dealt with in III and IV. Guardianship is important because assistance may be denied applicants who are thought to be unable to manage their money payments without such supervision. Provision for defraying the cost of guardianship requires further study.

The appendix includes a note on methods of conducting studies of public assistance administration, twelve pages of tables of doubtful value and seven pages of selected reading references.

Atlas of the Mouth and Adjacent Parts in Health and Disease. Prepared by Maury Massler, D.D.S., M.S., Director of the Child Research Clinic, Assistant Professor of Histology and Lecturer in Stomatology, College of Medicine, and Isaac Schour, D.D.S., Ph.D., D.Sc., Professor of Histology and Head of the Department of Histology, University of Illinois College of Dentistry. Cloth. Price, \$2.50. No pagination, with 150 illustrations by Carl T. Linden. Chicago: Bureau of Public Relations, Council on Dental Health, American Dental Association, [n. d.].

This book, with its fine plates and concise text, is the answer to a very real need in medical literature. Too little is known by the physician of the tooth and mouth in relation to health and disease, and too often the knowledge of the dentist is restricted to the tooth itself. The "Atlas of the Mouth" could be called the missing link in dentomedical relations. The illustrations—some of them in color—are partly original and partly modifications of published material. The text gives full and clear information by a clever use of large and small type. The selection of the material presented is the result of long experience in teaching dental and medical students. Anatomy, embryology, histology and pathology are combined to transmit useful knowledge applicable to the practice of dentist as well as of physician.

The first part of the book deals with the tooth. Its structure and development, including the chronology of tooth formation, are the basis for the discussion and illustration of caries, erosion, fluorosis, enamel hypoplasia and the changes in congenital syphilis. The lesions of the oral mucosa follow, including periodontal diseases and changes of the tongue. In the plates on tongue anatomy and pathology, diagrammatic pictures of the microscopic changes are included as insets to most of the microscopic illustrations, adding much to the understanding of any lesion. The anatomy of the oral glands is illustrated by plates of the tonsils, paranasal sinuses, arteries, veins and nerves of the head, mandibular articulation, muscles of mastication and their applied anatomy with regard to fractures of the mandible, ailments of the throat and many other disturbances.

To predict great success for this book and to recommend it to every physician and dentist is the pleasant duty of the reviewer.

Industrial Ophthalmology. By Hedwig S. Kuhn, M.D. Cloth. Price, \$6.50. Pp. 294, with 114 illustrations. St. Louis: C. V. Mosby Company, 1944.

In the introduction the author makes the statement that "industrial ophthalmology as a special field has not been previously dealt with as a comprehensive treatise," and "many monographs apposite to this field have been published." Both of these statements bear scrutiny. Throughout the long and stilted introduction there are many statements made, based on the author's limited field of industry—without reference to the work of others—which show a peculiarly mixed medical and psychologic approach to the problem of industrial ophthalmology. Industrial medicine has come into its own only in the past ten years, stimulated more recently by the war with the enormous increase in defense plants. Previous to the augmentation of the so-called heavy industries, with which the author is entirely concerned, there existed in this country many and various lighter industries, which also have been increased. Many of the latter have had industrial eye programs for years which are much simpler and more workable than that outlined [sic] by the author. The excellent work accomplished by such industries as

the Pullman Company, Sears, Roebuck and Company and the General Motors Company are given scant attention. The subject of illumination in industry, as it concerns the eyes, is given approximately two pages, while the literature on this subject fills volumes. Chapter iv, on industrial eye injuries caused by solid bodies, written by Dr. Albert C. Snell, which contains a treatise concerning sulfonamide drugs in ocular infections, is excellent. There are many illustrations showing the various jobs and machinery used in the heavy industries. The average industrial ophthalmologist and certainly the industrial physician will find little of use, except for the chapter by Dr. Snell, in this very unpractical monograph.

The History of Miners' Diseases: A Medical and Social Interpretation. By George Rosen, M.D. With an introduction by Henry E. Sigerist, M.D. Cloth. Price, \$8.50. Pp. 490, with 19 illustrations. New York: Schuman's, 1943.

The publication of a history of the development of industrial medicine in such an essential industry as mining is appropriate at this time, when the practice of this branch of medicine has become such a vital part of national defense measures.

By correlating the development of miners' diseases through the ages with the advances in the basic medical sciences and with the varying social and economic conditions that have contributed to the rise of occupational diseases in the industry, Dr. Rosen has provided an essential and interesting background for the medical discussion.

Although, according to the author, ancient medical writers do not mention the health hazards connected with the occupation of mining, glimpses given by other writers of the social and economic conditions under which the miners lived and worked indicate that these hazards were appalling. These conditions, combined with the physical deprivations and tortures to which the ancient miners were subjected, must have resulted in the rapid development of disease and premature death. In fact, mining conditions were still so bad at the time of Ramazzini (about the beginning of the eighteenth century) that he wrote "Whatever metal they mine they invite dreadful diseases which too often mock at every remedy, even supposing that some suitable remedy is duly prescribed; though it would seem to be a question whether it can be considered a pious duty to administer medical aid to men of that class and thus prolong their lives to the bitter end." The fact that mining in antiquity was done almost exclusively by slaves may account for the almost complete disregard of the miner and his diseases by ancient medical authors. Only the Corpus Hippocraticum and Galen refer to mine workers. All other references to the diseases of miners are found in the nonmedical writers of the Roman period.

It is significant that the early medical writers who discussed miners' diseases—Agricola, Paracelsus, Pansa, Stockhausen and others—had actual mining experience or had observed personally the miners among whom they lived and practiced medicine.

The discussion of the evolution of mining methods and miners' organizations from prehistoric times to the end of the nineteenth century should appeal especially to those connected with the mining industry. The general reader who likes biography and history and is interested in the progress of civilization will find the book instructive and stimulating. For those concerned with the prevention of occupational diseases—doctors, engineers and chemists—it will provide a historical background and much useful information for their specialized activities.

Office Endocrinology. By Robert B. Greenblatt, B.A., M.D., C.M., Professor of Experimental Medicine, University of Georgia, School of Medicine, Augusta. With a foreword by G. Lombard Kelly, M.D., Dean, University of Georgia School of Medicine. Second edition. Cloth. Price, \$4. Pp. 243, with illustrations. Springfield, Ill., & Baltimore: Charles C. Thomas, 1941.

This book is not intended as a textbook but represents a series of lectures presented to postgraduate classes in office endocrinology. The material is offered in abbreviated form and contains a minimum of theoretical and experimental data. If used with the understanding that textbooks should be used for reference, the manual will be well received and found useful by many in general practice. Each chapter offers a bibliography that will do much, if used, to offset the brevity of the book. The index is complete.

The Problem of Changing Food Habits. Report of the Committee on Food Habits 1941-1943. Carl E. Guthe, Chairman. Margaret Mead, Executive Secretary. Bulletin of the National Research Council, Number 108, October 1943. Paper. Pp. 177, with 3 illustrations. Washington, D. C.: The National Research Council, National Academy of Sciences, Inc. d.j.

This booklet outlines the problems confronting this country in the matter of making the most of our food supplies in the face of impending war. As part of the attack on these tremendous problems, the Committee on Food Habits of the National Research Council was organized to work with governmental agencies to determine wherein lay the weaknesses of the national dietary and how they might be corrected. Cultural as well as scientific problems were involved. Studies were made first of all to determine the food pattern of population groups with different racial backgrounds. Then the types of meals served to family groups and individuals were considered. It was demonstrated that a dietary change could be effected more readily when a group decided to do so rather than when it was asked to change. More desirable results are usually attained by contact with preexisting organizations than through new alignments. In general it was found that changes in food habits can be brought about in a relatively short time. The eating habits of such groups as shift workers, governmental office workers and racial groups were determined. Attitudes of the people of this country toward food rationing were sounded out with a series of carefully chosen questions, but essentially none of the information gathered in this study is found in the report. The group comprising the committee represents widely varied interests and therefore brings many points of view to the discussion of the problems. The results of the broad scope of these field studies and the numerous planned discussions should prove of real value in devising plans for the most effective utilization of this country's food supplies.

Die epidemische Kinderlähmung (Poliomyelitis). Von Prof. Dr. med. E. Glanzmann, Professor für Kinderheilkunde an der Universität Bern. Akademischer Vortrag gehalten am 26. Februar 1943. Paper. Price, 6.80 Swiss francs. Pp. 80, with 22 illustrations. Bern: Medizinischer Verlag Hans Huber, 1943.

This is an academic lecture at the University of Bern, Feb. 26, 1943, and now somewhat enlarged. The epidemiology, the etiology and genesis, the clinical features, the prevention and the treatment of infantile paralysis are discussed interestingly in the light of observations and experimental investigations. Particularly interesting are the sections dealing with the evolution of infantile paralysis from sporadic cases into widely distributed epidemics and with the origin and spread of epidemic outbreaks. The epidemics in Switzerland are shown on colored maps. The lecture presents well the present knowledge and understanding of infantile paralysis.

A Textbook of Materia Medica, Pharmacology and Therapeutics. By Harold N. Wright, M.S., Ph.D., Associate Professor of Pharmacology, University of Minnesota, Minneapolis, and Mildred Montag, B.S., M.A., Director, Adelphi College School of Nursing, Garden City, N. Y. Third edition. Cloth. Price, \$3. Pp. 706, with 93 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This book is intended for nurses but is better than many others offered for this purpose. The subject matter is presented in interesting style and is sufficiently complete to provide almost all that is essential for nurses studying the use of drugs. In fact, it is also a practical reference source for graduate nurses. The drugs are grouped according to their effects on the body tissues. Each chapter contains at the end a list of questions for practical exercises. The index is complete, as is the glossary of definitions.

Vascular Responses in the Extremities of Man in Health and Disease. By David I. Abramson, M.D., F.A.C.P. Cloth. Price, \$1. Pp. 412, with 59 illustrations. Chicago: University of Chicago Press, 1941.

The book is an excellent review of the subject, with particular reference to the underlying physiologic disturbances and the technic of arriving at a diagnosis. The work is written entirely from the standpoint of a physician without apparently very much personal experience from the evaluation of surgical procedures. A valuable part of the monograph is the extensive bibliography which follows each chapter. The book is generally well set out and is recommended to all students of vascular diseases.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

NAIL POLISH DERMATITIS AND SENSITIZATION TO SULFONAMIDES—HAIR LACQUER DERMATITIS

To the Editor:—What is the present status of dermatitis from nail polish and from hair lacquer?
M.D., Illinois.

ANSWER.—Numerous examples of nail polish dermatitis are still seen. In a paper by Keil and Van Dyck (*Arch. Dermat. & Syph.*, to be published) there is recorded hypersensitivity to a particular resin, namely toluene sulfonamide formaldehyde resin, in 25 cases of nail polish dermatitis. This is the chief cause of nail polish dermatitis as seen today. There are, however, exceptional cases in which this substance can be ruled out definitely as the cause. Toluene sulfonamide formaldehyde resin is used in many other types of lacquer. What is especially interesting is that 7 out of 16 persons tested with toluene sulfonamide (probably a mixture of the ortho and para varieties) were hypersensitive to that substance. The concentration used in testing by the patch technic was only 3 per cent in acetone. This substance is similar to sulfanilamide and differs only in the presence of a methyl group instead of the amino group in the para position. In a letter published in *THE JOURNAL*, Nov. 27, 1943, page 857, Keil suggested that this similarity might lead to a group reaction to sulfanilamide. In the paper to appear in the *Archives of Dermatology* it is recorded that 1 out of 4 cases showed this group hypersensitivity, and this case is especially interesting in that sulfanilamide had never been used before, either internally or externally. There is suggestive evidence that sensitization of this type carries with it the possibility of being group sensitized to the sulfonamides, but how frequently this occurs remains to be determined. Examples of this type of dermatitis are still being seen with considerable frequency.

The problem of hair lacquer dermatitis seems to be separate and distinct from that of nail polish. Cases of such dermatitis are, however, still too frequent.

EXCESSIVE MENSTRUAL FLOW PROBABLY FROM HEMORRHAGIC DISORDER

To the Editor:—A woman aged 32 complains of intermittent fever ranging as high as 102 F. oral at irregular intervals; excessive bleeding from a dental extraction, cuts, and so on since childhood; profuse menstruation, often requiring three to four dozen pads with prolonged periods, usually two to three weeks apart; easy bruising; cyanosis of the lips almost constantly—cyanosis involving the upper extremities at times. She has 2 children. Physical examination did not reveal significant factors except that she was pale and underweight and that the lips were cyanotic. There was no evidence of fibroids of the uterus or of cancer. Laboratory examination revealed a hemoglobin of 12 Gm., and this was confirmed by repeated examinations. The white blood cell count was 10,900 with a normal differential count. There were no abnormalities in the red cells. Bleeding time was 4.5 minutes and clotting time 9 minutes. There was poor clot retraction. The sedimentation rate was 1.2 mm. per minute. Hematocrit was 35 per cent. Plasma ascorbic acid was 0.4 mg. per hundred cubic centimeters. The basal metabolic rate was 1 plus. The Kahn reaction was negative. Agglutination tests for typhoid, paratyphoid and undulant fever were all negative. X-ray examination of the chest showed calcified Ghon tubercle at the right base and right hilar calcified adenopathy. There was no evidence of active pulmonary disease. The previous history indicates that the patient has passed many urinary calculi. X-ray examination of the kidneys (intravenous pyelogram) showed no abnormalities. The patient had an abdominal operation four years ago, at which time a uterine suspension was done. The tubes were kinked by adhesions, but other abnormalities were not noted. She has had attacks of sinusitis as well as middle ear infection. In an effort to check the severe menorrhagia she has had vitamin K, ascorbic acid, calcium and bile salts as well as roentgen treatment of the ovaries. What further investigations would be helpful? What therapeutic measures could be used to regulate the bleeding and clotting time. Is one justified in doing a hysterectomy in order to stop the bleeding or would severe hemorrhage occur elsewhere?
G. W. Brown, M.D., Buchanan, Mich.

ANSWER.—From the history it appears that the patient has a hemorrhagic disorder which is responsible for the excessive menstrual flow. The bleeding time is slightly prolonged, whereas the coagulation time is within normal limits (assuming that it was performed on venous blood by the Lee and White method). A platelet count should be made, as a reduction in platelets is frequently associated with a poor clot retraction. To complete the study of the hemorrhagic condition, determinations of the prothrombin and fibrinogen in the blood should be

made and the capillary resistance measured by a Rumpel-Leede test.

In ruling out undulant fever, the intradermal reaction would be of more help than the agglutination tests. One wonders whether the fever, cyanosis and hemorrhagic tendency are in some way related. A drug might produce both cyanosis and purpura.

It is possible that the patient has a hereditary hemorrhagic diathesis known as pseudohemophilia or thrombasthenia. If so, the only therapeutic measure of any value is blood transfusion, the effect of which is temporary. The production of an artificial menopause by further irradiation of the ovaries would seem to be the most conservative method of approach. Injections of testosterone have also been used to stop menstruation. Hysterectomy should be performed only as a last resort.

IRRITATION OF EYES FROM LOCAL INSTILLATIONS

To the Editor:—Can you tell me whether there is danger of chemical irritation to the eye in successive changes of treatment of acute catarrhal conjunctivitis by different clinic doctors on successive days with such instillations as mild protein silver, sulfathiazole ophthalmic ointment 5 per cent, yellow mercuric oxide, mercury bichloride ointment 1:3,000, metaphen, mercurchrome 1 per cent, hexylresorcinol, cerillavine solution 1:2,500, zinc sulfate 0.25 per cent solution and copper sulfate 1:1,000 ointment? Actually I have seen only changes from mild protein silver to sulfathiazole with yellow mercuric oxide to the lids, but with all drugs available is there not needed a special warning of danger from special chemical combinations?
M.D., New York.

ANSWER.—Presumably the writer of the query has in mind particularly (a) chemical irritation due to drug incompatibility or (b) changes in the tissues following the use of one drug which make that tissue particularly sensitive to another drug.

The chemical treatment of inflamed tissue is used (1) to reduce the viability of the infecting organisms (bacteriologic study should always be made so that specific treatment can be applied whenever possible, e. g. Klebs-Loeffler bacilli, gonococci, Morax-Axenfeld bacilli, (2) to increase the general immune and antibody content within and around the living cells or (3) to restore the tissues to normal at the earliest possible date.

How do chemicals act? First of all there is the specific action, which evidently is not in question. The various silver solutions are typical of those with nonspecific action. 1. Silver precipitates the salt of the tears and mucus; and the constant movement of the lids on the eyeball rolls this precipitate into stringy and fibrinous threads and moves them toward the inner canthus. 2. Depending on the strength of solution and the vigor of application, silver penetrates the superficial dead cells and may even kill some of the living cells. These then are thrown off and there follows active proliferation of the deeper lying cells. This activity calls for more nourishment; this means hyperemia and more edema; i. e. there is an increase in the amount of blood stream immune bodies. Within a few (two to twenty-four) hours, if the eyes are not kept closed (longer if they are), all of the seriously affected cells are thrown off and replaced by younger cells. One can follow this phenomenon by using the slit lamp and corneal microscope on corneal epithelium treated with 1 to 2 per cent silver nitrate. The new cells (a) are younger, more active and vigorous, (b) have fewer organisms in and among them and (c) have almost no precipitated silver. Therefore, the use, twenty-four hours later, of another element would present no problem of drug incompatibility.

Mild protein silver is much milder than silver nitrate and would present no problem of drug incompatibility. The other drugs similarly are less irritating. They were used originally, in part at least, as specifics. The sulfur drugs and zinc are still used specifically by many physicians. They all act for only a short time, as they are diluted, neutralized and thrown off by the tears and mucus which are present in great quantity in acute catarrhal conjunctivitis and which the treatment itself tends to augment. It must be concluded, therefore, that medication introduced into the conjunctival sac is not present in appreciable quantity a few hours later in cases of acute catarrhal conjunctivitis, so that drug incompatibility under the circumstances described is impossible.

Allergy and drug sensitivity exist or can be produced in the conjunctiva as well as in any other tissue. There is a time element here as elsewhere in the formation of such states; usually a week or more must elapse between the original sensitizing dose and the one producing the allergic reaction. Atropine conjunctivitis and mercurial conjunctivitis following surgical operation are well known examples. A number of persons react unfavorably to sulfathiazole, especially in 5 per cent solution or ointment. The reactions are specific; e. g., a mercurial does not sensitize a tissue to hexylresorcinol.

Another angle which must be considered as often complicating the picture is allergy from facial creams, eyelash prepara-

tions of many kinds, nail polish and even foods. Also regional skin disorders such as molluscum contagiosum and scabbie dermatitis are not infrequently encountered. Finally overtreatment must be avoided.

The answer to the question may thus be summarized: "Probably not; the fact that several physicians treat such a case in such diverse ways means that insufficient attention is paid to etiology and the study of inflammatory reactions."

FLUORINE IN WATER SUPPLIES AND DENTAL CARIES

To the Editor:—I have been disturbed about the current practice of advising fluorine filtered or distilled water for children in this area who are under 8 years of age. This has been done as a safeguard against "mottled enamel" in the second teeth, which is endemic here. According to past experimental and clinical observations, notably those of M. V. Smith as published in the University of Arizona Technical Bulletin in 1931, endemic dental fluorosis will occur in a certain percentage of children when the fluorine of the drinking water is 1 part per million. I am cognizant of the recent reports concerning dental caries being lessened by the presence of fluorine in the drinking water but have not seen any reports regarding the relative importance of the two evils or any opinion as to the overlapping of these two defects. What I am disturbed about is a statement I read in *Time*, April 24, to the effect that the health departments of the state of New York and the province of Ontario are adding fluorine to the drinking water of two cities to bring the fluorine content to 1 part per million as a test to prevent dental caries. Are the public health departments ignoring the possibility of dental fluorosis occurring or is there new work to show that dental fluorosis does not occur when the fluorine content of the water is 1 part per million?

D. C. Badger, M.D., Hobbs, N. M.

To the Editor:—I am interested in knowing the medical opinion of the use of fluorine in dental caries. If its use is advisable I should also like to know how to prescribe it.

J. J. McCarty, M.D., Chicago.

ANSWER.—The questions raised in these letters have been thoroughly investigated by Dean and his co-workers, who carried on an extensive epidemiologic survey on the relation of fluorine content in the water supplies to the incidence of mottled enamel and dental caries. Concentrations of fluorine of 1 part per million were found to be ideal in that this proportion prevents dental caries without producing dental fluorosis. In all communities where the water supply contained this concentration of fluorine the dental survey showed low dental caries rates and a low incidence of a mild mottled enamel. "Amounts of fluorine not exceeding 1 part per million of water are not considered of public health significance" (Dean).

The communities in New York which are undertaking the long range studies referred to are Newburgh and Kingston (New York news, *THE JOURNAL*, May 6, p. 73).

CORONARY INSUFFICIENCY AND DENTAL PAIN

To the Editor:—Periodically I encounter patients who complain of "pain in the teeth." These patients always show coronary insufficiency. They have as a rule the typical substernal, epigastric and arm pain and radiations. I realize that there are frequent references in the literature to pain in the jaws in coronary occlusion or thrombosis, but I cannot find any reference in which the complaint of "pain in the teeth" is encountered. The patients that I have seen with this complaint contend that they have a severe, painful sensation in the central six to eight teeth, both upper and lower. I should appreciate some comment on this finding.

M.D., Illinois.

ANSWER.—It is distinctly unusual in the experience of one who sees a great deal of coronary insufficiency to find that angina pectoris arising therefrom is referred to the teeth. It is relatively uncommon for heart pain of anginal or other nature to be referred even to the jaws. There are striking exceptions, but they are decidedly uncommon. It would seem probable that any frequent finding of pain in the teeth in patients who have coronary insufficiency is to be attributed primarily not to heart disease but to other trouble of local dental origin or is due to neuralgia.

DIETHYLSTILBESTROL MALE HYPERSEXUALITY

To the Editor:—Has the drug diethylstilbestrol been used in place of a sedative for male patients who show hypersexual activities while in an institution? I have not been able to find any articles in the literature.

George L. Kennedy, M.D., Foribault, Minn.

ANSWER.—A report on the use of diethylstilbestrol in a man with hypersexual activity while in a hospital will be found under the title of "Stilbestrol Induced Gynecomastia in the Male" in *THE JOURNAL*, Dec. 28, 1940, page 2263, by Dr. C. W. Dunn. There have been no extensive reports of such treatment in the literature. The implications in the more recent attempts to use diethylstilbestrol for the alleviation of prostatic carcinoma and metastases would give further credibility to this type of therapy.

SEVERE HAY FEVER WITH EXPECTED PARTURITION AT HAY FEVER SEASON

To the Editor:—A woman aged 26 is pregnant for the first time and expects her baby around October 1. For the last ten years she has suffered from fall hay fever from September 1 to October 1. Perennial injections with a special mixture containing ragweed and house dust gave no relief in 1942 or 1943. The father also has fall hay fever but is more violently allergic to ragweed than is the mother. Two siblings of the father also have ragweed sensitivity, as manifested by fall hay fever. The patient's pregnancy to date has been completely uneventful. Blood pressure is 114/76; urine is normal. Pelvic measurements reveal an ample gynecoid pelvis. Hemoglobin is 90 per cent. What treatment if any is indicated for her hay fever this year other than purely symptomatic measures? Would desensitization tend to affect the fetus adversely? Is induction of labor at the start of the ninth month (September 1) advisable to prevent parturition during the hay fever season? Would such induction alter the chance of transmission of allergy?

Milton L. Bonkoff, M.D., Michigan City, Ind.

ANSWER.—While pollen injections do not affect the fetus adversely, it would seem advisable in a case like this to discontinue attempts at hyposensitization during pregnancy. The reason for discontinuing such treatment is that perennial hyposensitization has failed to give relief.

It is true that some workers in allergy report better results with preseasonal than with perennial treatment in some cases. However, since the first year of treatment in this case may be considered as typical preseasonal treatment and since this failed to give any relief, it would seem advisable not to continue with such treatment. Relief can be given by symptomatic therapy.

There is no reason for preventing parturition during the hay fever season by earlier induction of labor. It would in no way alter the chances of transmission of allergic tendencies, since such transmission is based on hereditary factors.

EXAMINATION OF URINE

To the Editor:—What advantages are there in examining a fresh specimen of urine with and without ordinary urinary preservatives? What is the number of hours that a specimen may be considered "fresh" in order to retain the advantages mentioned? How many of the findings in a specimen of urine may be missed because the examination is made when the specimen can no longer be called a fresh specimen?

M.D., Pennsylvania

ANSWER.—For accurate examination urine should be examined fresh or else after preservation by cold or chemicals. At room temperature or higher urine begins to decompose rapidly, and after a few hours the various findings may change. Sugar may disappear rapidly. The reaction becomes increasing in acidity or alkalinity or perhaps changes from one to the other. Urea may decrease in amount. Volatile substances are lost. Casts may dissolve in a few hours. Gershenfeld (*Urine and Urinalysis*, Philadelphia, Lea & Febiger, 1943) says that specimens which are not properly preserved should be examined microscopically within six hours. At times substances usually not present are formed. Naturally since the decomposition is due to bacteria there is a large increase in bacteria; so any bacteriologic examination must be made on fresh or refrigerated urine. The period that urine may be kept without preservatives depends on the weather, but under ordinary conditions six hours is the outside limit and two hours is the preferable limit. Twenty-four hour specimens of urine that are sent through the mail should contain preservatives.

DERMATITIS FROM LOCAL ANESTHETICS

To the Editor:—I am allergic to butyn and to procaine hydrochloride, getting a terrific contact dermatitis. Cocaine does not affect me, but in most cases I prefer not to use cocaine. Do you know of any local anesthetic besides cocaine which has a different chemical formula from that of procaine or of butyn, which I could use with impunity?

J. L. Doch, M.D., Hettlinger, N. D.

ANSWER.—Metycaine hydrochloride (benzoyl-γ-[2-methylpiperidino]-propanol hydrochloride) has a structural chemical formula that differs greatly from that of butyn and procaine and also from cocaine. It is a surface anesthetic and may be used for infiltration, block anesthesia and spinal anesthesia. It used for infiltration, block anesthesia and spinal anesthesia. It would be worth a trial in the case cited, since many dentists who have been troubled with procaine dermatitis have found that they can use metycaine satisfactorily. Reference: Lundy, J. S.: *Clinical Anesthesia*, Philadelphia, W. B. Saunders Company, 1942, page 30.

COMPOSITION OF DENTAL PLATE

To the Editor:—A patient requests information on the use and advisability of a stainless steel plate for teeth. Is it tasteless, and will the secretions of the mouth affect it? This is with regard to an upper plate.

John Conley, M.D., Fort Wayne, Ind.

ANSWER.—The patient probably has in mind the chrome-nickel alloy plates. These are tasteless and are not affected by the secretions of the mouth.

THE EFFECT OF SMOKING CIGARETS

AND OF INTRAVENOUS ADMINISTRATION OF NICOTINE
ON THE ELECTROCARDIOGRAM, BASAL METABOLIC
RATE, CUTANEOUS TEMPERATURE, BLOOD PRESSURE
AND PULSE RATE OF NORMAL PERSONS

GRACE M. ROTH, PH.D.

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

CHARLES SHEARD, PH.D.

ROCHESTER, MINN.

The effect of the smoking of tobacco on the circulation of man has been the subject of many excellent papers. Comprehensive investigations of the pharmacologic and physiologic action of tobacco smoke and nicotine have been reported elsewhere and are not within the scope of this paper.

The vasoconstrictor action of smoking tobacco was first demonstrated by Bruce and his associates¹ in 1909 by means of the plethysmograph. Hesse² in 1907 and Lee³ in 1908 had observed that smoking produced an elevation of the blood pressure and an increase of the pulse rate. Since that time it has been further recognized that the smoking of cigarettes produces vasoconstriction characterized by a decrease of cutaneous temperatures of the extremities or plethysmographically by a decrease of the velocity of blood flow together with an elevation of blood pressure and pulse rate. Renewed interest in the effects of the smoking of cigarettes arose as a result of its alleged etiologic relation to peripheral vascular disease.

Maddock and Coller⁴ and Maddock, Malcolm and Coller⁵ in a series of papers demonstrated that smoking produced vasoconstriction of the peripheral blood vessels of the extremities and elevation of the blood pressure and pulse rate not only of patients suffering from peripheral vascular disease but also of normal subjects. Further, they demonstrated that intravenous injections of nicotine produced similar changes in nor-

mal persons. Barker⁶ in 1933 observed a significant vasoconstriction in the digits of normal subjects after they had smoked cigarettes. He reported that the effect was apparently due to the absorbed portion of the tobacco smoke and not to the smoke from the cigarette paper. In the same year Wright⁷ and in 1934 Wright and Moffat⁸ noted similar changes in cutaneous temperatures of the extremities and vasoconstriction of the capillaries of the nailfolds with smoking of both standard and denicotinized cigarettes. "An ashless filter paper cigarette produced no appreciable effects on the surface temperature." In contrast Mulinos and Shulman,⁹ who used the capillary microscope, the plethysmograph and the cutaneous temperature of fingers to determine the effect of smoking on the peripheral circulation, concluded that the greater part of the observed decrease of peripheral blood flow could be accounted for by deep breathing. Smithwick¹⁰ likewise reported a decrease of blood flow through a finger after a deep breath, immersion of the contralateral hand in cold water, a loud noise or even an unpleasant thought.

Weatherby¹¹ also found that such stimuli may cause changes of cutaneous temperature comparable to those produced by smoking. However, he found that vasoconstriction took place after the smoking of standard cigarettes but that when nicotine was removed from standard cigarettes and the denicotinized cigarettes were smoked the vasoconstriction was abolished almost completely. Restoration of the original nicotine content to such cigarettes restored the original effects, indicating that nicotine is the most important agent which contributes to the circulatory and cutaneous changes. Weatherby also noted that when his subjects were ambulatory vasoconstriction of the peripheral blood vessels did not occur during the smoking of standard cigarettes.

In contrast Evans and Stewart¹² found a similar decrease of peripheral blood flow with reduction of cutaneous temperatures of the extremities as a result of the smoking of standard cigarettes, denicotinized cigarettes or cigarettes not containing any nicotine (corn silk). They attributed these changes to sympathetic stimulation brought about by the irritating effect of smoke on the respiratory tract and not due to the nicotine content of the cigarette.

Simultaneously, Johnston¹³ in England added to the nicotine hypothesis by assuming that the smoking of tobacco is essentially a means of administering nicotine. He gave nicotine both hypodermically and intravenously and obtained a vasoconstrictor effect similar to that of smoking tobacco.

Because of the apparent lack of agreement among the various investigators and the importance of this subject to the clinician, further study of the subject seemed desirable.

PROCEDURE

Sixty-six observations were made on 4 male physicians and 2 female technicians whose ages ranged from 22 to 41 years. All were habitual smokers and inhaled during smoking. As they were accustomed to the procedures in the psychrometric room, psychic stimulation was at a minimum.

Standard cigarets of different brands bought on the open market were used. As a control, cigarets made of corn silk were smoked. Also comparative studies with standard cigaret paper and French ashless cigaret paper were made with equal weights of standard cigaret tobacco and corn silk to investigate the possibility of an irritating factor in the preparation or bleaching process of the paper. Also a popular British cigaret filter holder was used with standard cigarets.

Data were obtained in a constant temperature room with an environmental temperature of 78 F. and a relative humidity of 40 per cent. The subjects were fasted for fifteen hours previous to the tests, and during the test they wore lightweight short pajamas and except when otherwise noted were in the supine position on comfortable beds.

The temperatures¹⁴ of the plantar surface of the first and third toes of both feet and the volar side of the distal phalanges of the first and third fingers of both hands were measured by means of thermocouples¹⁵ of copper and constantan. When fairly constant readings of the cutaneous temperatures had been obtained and determinations of basal blood pressure and pulse rate had been made, smoking was begun. Two cigarets were smoked in succession until two thirds of each had been smoked. Simultaneous determinations of blood pressure, pulse rate and cutaneous temperature were obtained at one minute intervals during the smoking period, which generally lasted about twelve to sixteen minutes. The subjects inhaled the tobacco smoke with their accustomed depth and frequency. Further, the observations were continued for thirty minutes to one hour after smoking. An attempt was made to avoid all unnecessary noise and other stimuli which might produce vasoconstriction during this period.

Observations were divided into six groups:

GROUP I. *Cutaneous temperatures while the subjects were resting in the supine position wearing lightweight short pajamas.* The cutaneous temperatures of the extremities were observed before and after the smoking of two cigarets of the four types of cigaret previously mentioned. The British filter holder also was used. As a further control, puffing an unlighted cigaret was

tried on several occasions to determine the effect on the cutaneous temperatures of the extremities. In many instances the oral temperature was noted before and after smoking, and in several instances rectal temperatures were recorded simultaneously with those of the fingers and toes. On one occasion twenty thermocouples were used and peripheral blood flow was calculated according to the method of Hardy and Soderstrom.¹⁶

GROUP II. *Cutaneous temperatures of the extremities of fully clothed subjects while sitting or during slow walking.* Determinations of the cutaneous temperatures were made by placing thermocouples inside the socks and shoes. The subjects sat in a comfortable chair with a back rest for a thirty minute control period. Two standard cigarets were then smoked. For slow walking a similar control period was employed while the subject averaged four short steps backward and forward for each three seconds. Again two standard cigarets were smoked and the usual observations made.

GROUP III. *Basal metabolism.* The basal metabolic rate was first determined, then two standard cigarets were smoked and the determination of the basal metabolic rate was repeated immediately after the smoking had been finished. Similar observations with corn silk were made for comparison. Studies of the cutaneous temperatures of the extremities were carried out in most instances.

GROUP IV. *Electrocardiography.* Electrocardiographic tracings were made before and after the smoking of two standard cigarets and at another time after the smoking of two corn silk cigarets for control.

GROUP V. *Intravenous administration of nicotine.* After basal determinations of the cutaneous temperatures of the extremities had been noted, an infusion of isotonic solution of sodium chloride was started. When basal readings had been observed under these circumstances, without the subject being aware of the change, 2 mg. of nicotine was given through the same apparatus. Electrocardiographic tracings were obtained at several intervals before, during and after the infusion of isotonic solution of sodium chloride and nicotine. The determinations of cutaneous temperature were discontinued during the taking of the electrocardiograms except in 1 instance but were resumed after the tracings had been made.

GROUP VI. *Blood pressure including the cold pressor test and pulse rates.* Determinations of blood pressure and pulse rates were made simultaneously with the observations of cutaneous temperature in all the foregoing groups. In addition a cold pressor test was done on each subject. The method of Hines and Brown¹⁷ was employed. After basal blood pressures had been obtained one hand was immersed well above the wrist in water at 4 C. for one minute and the response of the blood pressure was noted during this period. This was done to determine whether any parallelism existed between the reactivity of the blood pressure to the cold pressor test and hypersensitiveness to tobacco.

RESULTS

GROUP I. *Cutaneous temperatures while the subjects were resting in the supine position wearing lightweight short pajamas.* When an unlighted cigaret was puffed for the period it usually took to smoke two standard cigarets there was little or no change of the cutaneous temperature of the extremities. The average decrease of cutaneous temperature after the smoking of two standard cigarets was 1.8 degrees C. for the toes, with a range from 0.7 to 4.0 degrees C., while for the fingers it was 3.2 degrees C. with a range from 1.2 to 6.5

decrease which took place in any digit was 2 degrees C. (table 2). Figure 1 demonstrates graphically the comparison of puffing on an unlighted cigaret, smoking two corn silk cigarets and smoking two standard cigarets.

The effect of smoking two corn silk cigarets and two standard cigarets on the peripheral blood as determined by the method of Hardy and Soderstrom¹⁰ showed little change with the corn silk cigarets and the usual change with two standard cigarets. When French ashless cigaret papers were used with the amount of tobacco

degrees C. The maximal decrease for any one toe was 4.3 degrees C. and 7.7 degrees C. for a finger (table 1).

After the smoking of two standard cigarets the maximal rise of oral temperature was 0.6 degree C. Also the rectal temperatures were little changed in two observations on 1 subject. The actual rectal temperature ranged from 37.2 C. (98.9 F.) to 37.4 C. (99.3 F.) in 1 instance and changed from 37.4 C. (99.3 F.) to 37.8 C. (100 F.) at another observation. These changes could not be considered significant in the procedure and type of investigation with which we are concerned.

When two corn silk cigarets were smoked by each of 4 of the subjects on five occasions there was an increase of 0.1 to 0.7 degree C. in the toes in three observations and a decrease of 0.7 to 1.4 degrees C. in two observations. In the fingers there was a decrease of 0.4 to 1.1 degrees C. except in 1 instance, in which there was an increase of 0.3 degree C. The greatest

in a standard cigaret or with corn silk, the effect on the cutaneous temperatures corresponded to the effect produced by the respective cigarets alone. The British filter holder together with standard cigarets produced the same decrease of cutaneous temperature of the extremities as the standard cigarets did alone.

GROUP II. *Cutaneous temperatures of the extremities of fully clothed subjects while sitting or during slow walking.* Figure 2 demonstrates the effect of the smoking of two standard cigarets on the cutaneous temperatures of the extremities while sitting and during slow walking. In each instance there was a decrease of the cutaneous temperatures of the fingers and toes. Similar results were obtained for 2 other subjects.

GROUP III. *Basal metabolism.* As has been shown previously, there is a more or less linear¹⁸ relation

18. Sheard, C., and Williams, M. M. D.: Skin Temperatures of the Extremities and Basal Metabolic Rates in Individuals Having Normal Circulation, *Proc. Staff Meet., Mayo Clin* 15: 758-762 (Nov. 27) 1940.

between the cutaneous temperature of the toes and the basal metabolic rate. Figure 3 shows further evidence of this relation. After the smoking of two standard cigarettes the variation of the decrease of the cutaneous temperatures and the relation with the basal metabolic rate are evident. Figure 4 shows the effect of smoking

Fig. 1.—Effect of puffing on an unlighted cigarette, smoking two corn silk cigarettes and smoking two standard cigarettes on the cutaneous temperature of the extremities, blood pressure and pulse rate of the same subject. The cutaneous temperature curves of only one toe and one finger are shown. The control period in each instance was thirty minutes.

two standard cigarettes on the basal metabolic rate and the effect of smoking two corn silk cigarettes. For these particular subjects the basal metabolic rate increased with the smoking of two standard cigarettes and decreased with the smoking of two corn silk cigarettes.

GROUP IV. Electrocardiography. All tracings taken after the smoking of standard cigarettes resulted in an increase of heart rate averaging between 15 and 36 beats per minute. A decrease of the amplitude of the T waves was noted for all subjects. The average decrease was between 1 and 2 mm. in all leads, and in a few instances the T waves in lead 3 became isoelectric. The greatest decrease of amplitude of T waves was noted after the smoking of standard cigarettes. The tracings taken after the subject had smoked corn silk cigarettes did not show any increase of heart rate or, at most, 5 beats per minute. The majority of these

Fig. 2.—Effect of smoking two standard cigarettes on the cutaneous temperatures of the extremities, the blood pressure and the pulse rate of the same subject while sitting and during slow walking. Note the decrease of the cutaneous temperature.

tracings after the smoking of corn silk cigarettes did not show any change of amplitude of the T waves, the maximal decrease of amplitude of the T waves ranged between 0.5 and 1.0 mm. and in 3 instances there was a slight increase of amplitude of the T waves. Changes of amplitude of the QRS were negligible and

in no instance was there an increase of the PR or the QRS intervals. Figure 5 demonstrates the typical electrocardiographic changes on the same subject on different days under the foregoing conditions.

GROUP V. Intravenous administration of nicotine. With the intravenous administration of isotonic solution of sodium chloride for fifteen minutes previous to the injection of nicotine there was a slight decrease of the cutaneous temperature of the extremities of 2 of the subjects. After the administration of 2 mg. of nicotine there was a sharp decrease of the cutaneous temperatures of the extremities of all subjects, at least parallel to that of smoking two standard cigarettes and in 2 instances greater than that obtained by smoking two standard cigarettes. Figure 6 demonstrates the changes of cutaneous temperatures after the smoking of corn silk and standard cigarettes and after intravenous administration of nicotine.

The electrocardiographic tracings taken during the intravenous administration of isotonic solution of sodium chloride did not show any increase of the heart rate, and in 1 instance the tracing showed a decrease

Fig. 3.—Effect of smoking two standard cigarettes on the cutaneous temperature of the extremities, the blood pressure and the pulse rate of three different basal metabolic rate subjects. When the basal metabolic rate is low the cutaneous temperature of the toes is correspondingly low; when the basal metabolic rate is high the cutaneous temperature of the toes is high.

of the heart rate. There was either no change of the amplitude of the T waves or a maximal decrease of between 0.5 and 1.0 mm. After the intravenous administration of nicotine the tracings taken resulted in an average increase of heart rate of between 30 and 40 beats per minute. A decrease of amplitude of the T waves averaging between 1 and 3 mm. in all leads occurred in all subjects, and in a few instances the T waves demonstrated negativity in lead 3. Changes of amplitude of the QRS were negligible, and in no instance was there an increase of the PR or the QRS intervals. Figure 5 demonstrates the typical electrocardiographic changes on the same subject on different days under the foregoing conditions.

GROUP VI. Blood pressure including the cold pressor test and pulse rates. The average basal blood pressure for fourteen observations before smoking was 99 mm. of mercury systolic with a range from 90 to 120, while the average basal diastolic blood pressure was 69 mm. of mercury with a range from 60 to 85 (table 1). During the smoking of two standard cigarettes the average

blood pressure increased 19 mm. of mercury for the systolic and 14 mm. of mercury for the diastolic, with a range of 10 to 35 in the systolic and 6 to 20 in the diastolic. The average basal pulse rate was 69 beats per minute, with a range from 48 to 82 beats per minute. During smoking the pulse rate increased an average of 36 beats per minute, with a range from 20 to 52 beats per minute. When two corn silk cigarettes were smoked the average basal blood pressure was 99 mm. of mercury for the systolic and 62 for the diastolic (table 2). The average increase during the smoking of two corn silk cigarettes was 3 mm. of mercury in the systolic and 4 in the diastolic. The pulse rate likewise was increased only 4 beats per minute from the basal level of 70 beats per minute. This was in contrast to an increase of 36 beats per minute during the smoking of two standard cigarettes. There were 3 normal reactors to the cold pressor test and 3 hyperreactors to the cold pressor test.

COMMENT

While the subjects were resting in a supine position and smoking standard cigarettes there was a decrease of the cutaneous temperatures of the extremities, which

Fig. 4.—Effect of smoking two standard cigarettes and two corn silk cigarettes on the basal metabolic rates of 4 subjects. The fourth subject did not smoke corn silk cigarettes.

been performed we have observed the same results. In our observations the decrease of cutaneous temperatures continued for half an hour to one hour after smoking ceased. This decrease of cutaneous temperatures has been noted generally by other observers in similar studies. While a subject was smoking corn silk cigarettes the decrease of cutaneous temperatures was negligible, and similar results were observed by Weatherby¹¹ and by Maddock and Coller,¹⁹ using cigarettes without nicotine. Further, the effects of smoking corn silk cigarettes were not irritating, as evidenced by the absence of nasopharyngeal irritation and coughing. It was observed that French ashless cigarette papers with standard cigarette tobacco or the British cigarette filter holder did not nullify the decrease of cutaneous temperatures when the subject was smoking standard cigarettes. The latter observation confirms the previous report of Moyer and Maddock.²⁰

In these studies with standard cigarettes the decrease of the cutaneous temperature of the toes was less than that of the fingers. This difference may be due to the

effect of the small amount of nicotine on the sympathetic nervous system. Generally, in the simple heat regulatory mechanism of the extremities, vasoconstriction occurs first and more decidedly in the feet and later in the hands if there is a demand for further regulation.

Fig. 5.—Electrocardiographic tracings taken on the same subject on different days. In the tracings the heart rate is the same before smoking, after smoking corn silk and while receiving saline solution intravenously, and the amplitude of the T waves does not vary more than from 0.5 to 1.0 mm. The heart rate after the subject had smoked two standard cigarettes was 100 beats per minute; while the subject was receiving nicotine intravenously the rate was 110 beats per minute. The amplitude of the T waves decreased about 1 mm. more as the result of intravenous administration of nicotine than during the smoking of two standard cigarettes. There was a definite decrease both from smoking two standard cigarettes and from the intravenous administration of nicotine, averaging between 1 and 3 mm.

We agree with Evans and Stewart¹² that little or no change took place when the subject puffed on an unlighted cigarette with the normal depth and frequency used in smoking. The degree of response to smoking varies among individuals and for the same subject from day to day, which was also observed by Wright and Moffat⁸ and by Mulinos and Shulman.²¹ As a result, new basal levels for each study must be obtained for blood pressure, basal metabolic rates and cutaneous temperatures.

Although most smoking occurs while a person is sitting or walking, it appears from the literature that

Fig. 6.—Effect of smoking two corn silk cigarettes, of smoking two standard cigarettes and of an intravenous injection of 2 mg. of nicotine on the cutaneous temperature of the extremities, the blood pressure and the pulse rate of the same person.

little work has been done under these conditions. Weatherby¹¹ found that the decrease of cutaneous temperatures after the smoking of standard cigarettes was

21. Mulinos, M. G., and Shulman, I.: The Effects of Cigarette Smoking and Deep Breathing on the Peripheral Vascular System Studied by Five Methods, *Am. J. M. Sc.* 190: 708-720 (May) 1940

neutralized by mild physical activity. In our subjects who were fully clothed and who smoked while sitting the usual drop of cutaneous temperature and increase of blood pressure and pulse rate occurred. When our subjects were clothed and were allowed to walk about the psychrometric room after the smoking of two standard cigarettes the decrease of cutaneous temperatures of the toes and fingers and the increase of blood pressure and pulse rate were the same as while the subjects were at rest under basal conditions.

The basal metabolic rate increased after our subjects had smoked standard cigarettes under basal conditions. These results are similar to those of Goddard and Voss²² and of Evans and Stewart,¹² who found an increase in 69 per cent of their subjects. Three of our subjects, smoking corn silk cigarettes, showed a decrease of basal metabolic rate. These changes may be significant, since Main²³ has observed that the alveolar carbon dioxide tension was lowered after the smoking of standard cigarettes, while nicotine free cigarettes produced very much less effect.

When the subjects smoked standard cigarettes the most common changes in the electrocardiographic tracing were an increase of heart rate and a lowering of the amplitude of the T waves in all leads. Similar changes were observed by Graybiel, Starr and White,²⁴ although their subjects smoked only one cigaret before the tracing was taken. They ascribed these changes to the action of the nicotine on the cardiac ganglions, and they also found that these changes were similar to those observed in atropinization. Therefore they concluded that nicotine causes parasympathetic paralysis and sympathetic stimulation. When our subjects smoked corn silk cigarettes there was a negligible increase of heart rate with no appreciable lowering of the amplitude of the T waves; in fact in some instances there was a slight elevation. In contrast, Evans and Stewart¹² found a decrease of amplitude of the T waves in 71 per cent of their cases after their subjects had smoked corn silk cigarettes, fully denicotinized cigarettes and commercially denicotinized cigarettes. They also found an increase of pulse rate and blood pressure, which was not apparent in our subjects who smoked corn silk cigarettes. When isotonic solution of sodium chloride was given our subjects intravenously there was a slight decrease of amplitude of the T waves, but when nicotine was given through the same apparatus without the subject's knowledge of the change the increase of the heart rate and the decrease of the amplitude of the T waves were even greater than those which occurred after the subject had smoked two standard cigarettes.

During the intravenous administration of isotonic solution of sodium chloride the cutaneous temperatures, particularly of the toes, decreased slightly but a basal level was soon attained. With the introduction of the nicotine into the isotonic solution of sodium chloride without the subject being aware of the particular time of the injection of the nicotine, cutaneous temperatures of the extremities decreased in a similar manner to that obtained after the smoking of two standard cigarettes, but the decrease was more rapid and of greater mag-

nitude. As this decrease did not occur while the subject was smoking corn silk cigarettes, it appears that the effect may be due primarily to the nicotine content of standard cigarettes. These results are similar to those previously obtained by Maddock and Coller¹⁹ and by Moyer and Maddock²⁰ and are interesting in the light of the studies of Haag,²⁵ who found while working with animals that the effect of smoke solutions was proportional to their nicotine content.

It appears that intravenously administered isotonic solution of sodium chloride has little effect on the electrocardiographic tracing but that 2 mg. of intravenously administered nicotine accounts for the changes observed. Many investigators have observed that either stimulation of the sympathetic nerves or injection of epinephrine causes an increase of amplitude of the T waves, while stimulation of the vagus nerves or the injection of acetylcholine causes a decrease of their amplitude. As stated previously, changes of the T waves after administration of nicotine are similar to the changes resulting from atropinization. It appears likely that the action of nicotine on the vagus and sympathetic ganglions would account for the increase of blood pressure and pulse rate. Whatever adjustment the heart makes for increase of blood pressure and pulse rate must account for the decrease of amplitude of the T waves, and the latter phenomenon did not occur in the absence of nicotine.

While our observations were carried out on normal subjects, similar decreases of amplitude of the T waves, although of greater magnitude, have been observed in persons suffering from coronary disease during anoxemia tests, as performed by Patterson and his co-workers,²⁶ who used 10 per cent oxygen with nitrogen for as long as fifteen to twenty minutes. However, anoxemia appears unlikely to be the causative factor of the changes that we observed, since evidence has been given that the alveolar carbon dioxide tension was lowered after the smoking of standard cigarettes.

The blood pressure and pulse rate were increased in all our subjects as a result of smoking standard cigarettes, confirming previous observations of many investigators. The increase persisted while the subject was smoking and not longer than fifteen minutes after he stopped smoking. However, there was no increase of blood pressure or pulse rate as the result of smoking corn silk cigarettes. This observation was noted by Main²³ and by Maddock and Coller¹⁹ using nicotine free cigarettes but is at variance with the results of Evans and Stewart,¹² who obtained similar increase with corn silk and denicotinized cigarettes. It was found that French ashless cigaret papers and a popular British cigaret filter holder used with standard tobacco gave the same results as when standard cigarettes were used alone, and that when they were used with corn silk they gave the same results as when corn silk was used alone. When nicotine was administered intravenously the increase of blood pressure and pulse rate was similar to that encountered after the smoking of two standard cigarettes.

Apparently the cold pressor test gives little if any insight into the reaction produced by tobacco on the blood pressure of a normal subject. One subject, a hyperreactor to the cold pressor test, was a normal

reactor to tobacco. Likewise, a normal reactor to the cold pressor test was a hyperreactor to tobacco. As other observers have seen, there are reactors to cold and reactors to tobacco. The blood pressure of other subjects reacted the same both to the cold pressor test and to tobacco.

After our subjects had smoked standard cigarettes it was found that the blood pressure and pulse rate and the electrocardiogram returned to normal within five to fifteen minutes. However, the peripheral vascular constriction indicated by the cutaneous temperatures of the extremities persisted from half an hour to an hour and in some cases much longer. These observations make us conclude, as did Maddock and Coller,¹⁹ that the smoking of standard cigarettes should be avoided in the presence of peripheral vascular disease. As Pratt²⁷ has suggested, the habit of giving an injured soldier a cigaret is not advisable if arterial injury has occurred, as segmental spasm of the artery is common in such trauma and the vasoconstriction in a person sensitive to tobacco may cause irreparable damage.

SUMMARY

Observations on six normal subjects yielded the following results:

1. When the subjects were resting in a supine position after smoking two standard cigarettes or French ashless cigaret paper with standard tobacco or standard cigarettes in the British cigaret filter holder the cutaneous temperatures of the extremities of all the subjects decreased. In contrast, when two corn silk cigarettes were smoked there was little if any change of the cutaneous temperatures of the extremities.

2. When fully clothed normal subjects were sitting or engaged in slow walking, the temperatures of the extremities also decreased to the same degree after the smoking of two standard cigarettes as while the subjects were in a resting, supine position.

3. An increase of the basal metabolic rate occurred after the smoking of two standard cigarettes, whereas the rate decreased after the smoking of two corn silk cigarettes.

4. Consistent changes of the electrocardiographic tracing developed after the smoking of two standard cigarettes. The changes consisted in an increase of heart rate and a lowering of the amplitude of the T wave. Such changes were negligible after the smoking of corn silk cigarettes.

5. When saline solution was given intravenously previous to the intravenous injection of nicotine there was at first a slight drop of the cutaneous temperatures of the extremities, but when nicotine was added to the solution the decrease was rapid and pronounced. After the injection of nicotine the electrocardiographic tracing demonstrated a definite increase of heart rate and a lowering of the T waves even greater than that seen after the subjects had smoked two standard cigarettes.

6. There was an increase of blood pressure and pulse rate after either the smoking of two standard cigarettes or the intravenous injection of 2 mg. of nicotine. After the smoking of two corn silk cigarettes there was little or no change of blood pressure and pulse rate.

7. While some subjects may show a parallelism between hyperreaction to the cold pressor test and hypersensitiveness to tobacco, many other persons may hyperreact to one or the other alone.

THE CAUSE OF DEATH IN RHEUMATIC HEART DISEASE IN ADULTS

ANTONIO JUCÁ, M.D.

FORTALEZA, BRAZIL

AND

PAUL D. WHITE, M.D.

BOSTON

Although rheumatic fever has been the subject of numerous and extensive studies, many aspects of its natural history still remain open to scientific investigation. This is particularly true with reference to rheumatic fever and rheumatic heart disease in adults, since the greatest number of investigations have been made on patients during their childhood and adolescence. The number of adults with rheumatic fever is not negligible. According to Cohn and Lingg¹ the percentage of these cases occurring in early maturity is 42, embracing, of course, the survivors from childhood (23 per cent) and adolescence (9 per cent) plus the new cases which occur at this age period (10 per cent).

D. Other causes related to the heart.....	14
E. Causes unrelated to the heart.....	6
F. Unknown causes.....	1
Total cases.....	100

* Of these 35 cases with congestive failure without evidence of acute rheumatic fever, 23 showed important complications, some of which were doubtless responsible for the congestive failure itself or for death; these complications were as follows: pulmonary infarction in 10 cases (7 with normal rhythm and 3 with auricular fibrillation), bronchopneumonia in 10 cases (5 with normal rhythm and 5 with auricular fibrillation) and auricular fibrillation in the remaining 5 cases. Thus auricular fibrillation was present in 13 of these cases.

The present paper submits an analysis of 100 unselected fatal cases of rheumatic heart disease over the age of 20 years at death and examined post mortem. They were collected from the records of the Massachusetts General Hospital and include patients from 1927 to 1943 inclusive. On looking at the figures one should take into account the cause of death. Since any one of two, three or four factors may be the cause of death, it is often difficult to ascertain which is the main determinant factor. Nevertheless we have made an effort to determine the cause of death as precisely as possible. The myocardium was examined for active rheumatism.

In an attempt to analyze these cases according to Bland and Jones's² classification of causes of death (in 306 young persons with rheumatic fever or its sequelae, the great majority of whom were children), our own results given in table 1 were obtained.

Grouped in decades at the time of death, the number of patients was classified as in table 2.

1. Cohn, A. E., and Lingg, C.: The Natural History of Rheumatic Cardiac Disease, *J. A. M. A.* 121: 1-8 (Jan. 2) 1943.

The duration in years as related to the age in decades at the onset of the disease is given in table 4.

The age at the time of death as related to the cause of death is given in table 5.

The sex as related to the cause of death is given in table 6.

The duration of the disease in the group of 57 patients as related to the cause of death is given in table 7.

In table 8 the valvular lesions and mean heart weight are distributed according to the cause of death.

In table 9 we have compared the figures which we obtained with those compiled by Bland and Jones.

COMMENT

In studying table 9 one may note that acute rheumatic fever as a cause of death occurs to a lesser extent in adults than in children; in the former group it was present in only 24 per cent of the cases, while in the latter group it was present in 75 per cent. Congestive failure without the exciting factor of acute rheumatic fever is a minor factor as a cause of death in children (only 7 per cent), while in adults it is the chief cause responsible for death (35 per cent). The latter figure is quite close to that given by Laws and Levine³ for patients from the Peter Bent Brigham Hospital. These writers, working on a group of 148 patients of which the youngest was 12 years old, encountered congestive

failure as a cause of death in 33.1 per cent of the cases. Martin,⁴ studying the cause of death in 431 children having rheumatic fever, found that 80 per cent of the deaths were due to rheumatic infection and less than 1 per cent to congestive heart failure.

The percentage of deaths in adults due to congestive failure deserves, nevertheless, a special comment concerning the concomitance of other factors which undoubtedly represent an important role in the death of such patients. We are referring particularly to pulmonary infarction, bronchopneumonia and auricular fibrillation. In a total of 35 cases of congestive failure, auricular fibrillation occurred thirteen times, bronchopneumonia or pneumonia ten times and pulmonary infarction ten times. One cannot underestimate the importance of auricular fibrillation as a precipitating factor in many cases of congestive failure. Arteriosclerosis and hypertension are still to be regarded as complicating elements in some instances. Thus there remain few patients for whose death congestive failure appears to be the only and isolated factor directly responsible.

Bacterial endocarditis was seen in 18 per cent of the patients. This is undoubtedly a high figure, but it probably represents an accurate one in daily practice with adult patients. For comparison one may note the

3. Laws, C. L., and Levine, S. A.: Clinical Notes on Rheumatic Heart Disease with Special Reference to the Cause of Death, *Am. J. M. Sc.* 186: 533-549 (Dec.) 1933.

4. Martin, A. T.: Twenty Years' Observation of 431 Children with Rheumatic Heart Disease, *J. A. M. A.* 117: 1663-1670 (Nov. 15) 1914.

figures given for children by Bland and Jones² (6 per cent), Stroud⁵ (6 per cent) and May Wilson⁶ (2 per cent). On the other hand, Davis,⁷ working in a mixed group of children and adult patients, encountered bacterial endocarditis in 13.7 per cent, and Laws and Levine,⁸ dealing only with patients over 12, in 29 per cent of the cases.

Classified in the group "other causes related to heart" are 5 cases of myocardial infarction, 3 of cerebral embolism and 1 of mesenteric embolism.

In the group "causes unrelated to heart" there are 1 carcinoma, 1 lymphoblastoma (Hodgkin's type), 2 aortic thrombus, 1 bronchopneumonia, 1 necrosis of the liver, 1 hepatic cirrhosis and 1 cholangitis.

The greatest mortality occurred in the fourth decade, that is, in patients between 30 and 39 years of age, the oldest patient being an 82 year old woman afflicted with aortic and mitral lesions, who died in congestive failure thirty-two years after the onset of her rheumatic heart disease. In this case, as in some reported by White and Bland,⁸ rheumatic lesions "may be regarded as largely of academic interest, provided rheumatic reactivation does not take place."

In the present series, with reference to sex in rheumatic fever, the figures obtained were analogous to the figures found in statistics dealing with many thousands of cases. In other words, the number of cases encountered in the two sexes is about the same.

The largest number of first attacks of rheumatic fever, more than 50 per cent of the total, occurred in the second decade, that is, between 10 and 19 years of age.

It is interesting to note that in the table in which we have recorded the duration of disease as related to cause of death the minimum duration was found in the group of bacterial endocarditis and the maximum in the group of causes unrelated to the heart.

In the table dealing with valvular lesions we see that in most of the cases there was involvement of several valves. It is also curious to note that in the group "bacterial endocarditis" the association of mitral and aortic lesions predominates. It seems that in rheumatic heart disease those patients who show the combination of mitral and aortic lesions are more likely to get bacterial endocarditis.

The heart weight was maximal in the series of patients who died in congestive failure and minimal for those of the group "causes unrelated to heart."

In a consideration of valvular lesions found at death, the average duration of life after the first attack of rheumatic fever was mitral 22, aortic 37, mitral and aortic 30, and mitral, aortic and tricuspid 18 years. One may infer from these figures that isolated aortic involvement is the best tolerated valvular lesion. The group with unassociated mitral lesions had an average of life shorter than the combined mitral and aortic lesions, but the number of cases in each group was inadequate for final conclusions in this respect.

SUMMARY

We have studied the cause of death in 100 unselected fatal cases of rheumatic heart disease over the age of 20 years. All of the patients were submitted to post-

mortem examination. The relationship of age, sex, expectancy of life, valvular lesions, and heart weight to the cause of death was considered. It was found that congestive failure without evident acute rheumatism accounted for 35 per cent of the fatalities, acute rheumatic fever and congestive failure for 22 per cent, bacterial endocarditis for 18 per cent, other causes related to the heart for 14 per cent, causes unrelated to the heart for 8 per cent, acute rheumatic fever alone for 2 per cent and unknown causes for 1 per cent.

BROMIDE INTOXICATION

WILLIS SENSENBACH, M.D.

WINSTON-SALEM, N. C.

In recent years many writers¹ have described the clinical picture of bromide intoxication and have emphasized the importance and prevalence of this condition. The effect of these writings on the incidence of bromide poisoning, however, appears to have been slight. Bromide intoxication continues to be a common condition for two reasons: (1) the uncontrolled sale of many different patented pain remedies, many of which contain sodium or potassium bromide, and (2) the widespread use of this drug for prolonged periods by practicing physicians. Apparently it is still not generally realized that bromides may produce severe intoxication, and the signs and symptoms of bromide intoxication are not always recognized when they appear. All too often the dosage of bromide is increased by the physician in order to combat the early signs of bromide intoxication; insomnia, restlessness, "dizziness," weakness and particularly headache, when the safer course would be to discontinue the drug and, if necessary, prescribe a different sedative. It should be remembered that bromides exert an accumulative effect and that bromide excretion and retention are intimately related to sodium chloride and fluid intake.

Of the 49 cases reported here the histories record that a physician was responsible for the excessive bromide intake in 28 instances. In 10 of the 20 cases seen at the North Carolina Baptist Hospital, and in 18 of the 29 cases reported from the Vanderbilt Hospital, bromide had been taken on the prescription of a physician. In most instances they were sent to the hospital by the physicians for diagnosis. Only 10 patients are known to have been poisoned because of excessive self medication with various patented pain remedies, including "Stanback," "B. C." and "Bromo-Seltzer." In 11 cases the source of the bromide was unknown.

My purpose in the present communication is to reemphasize the high incidence of bromide intoxication and to suggest, as others have previously done, that more caution be employed in the use of these compounds.

CLINICAL STUDY

From January 1943 to December 1943, 20 cases of bromide poisoning were treated in the medical wards of the North Carolina Baptist Hospital, a relatively small service of 40 beds. Few have been the days

during the past year when this service has not been the host to from 1 to 3 such patients. The patients who have been admitted to the hospital represent only the more severe intoxications. A number of milder cases have been treated in the outpatient department and are not considered here. In addition to the cases seen at the North Carolina Baptist Hospital, this report includes 29 cases diagnosed as bromide intoxication over a three year period at the Vanderbilt University Hospital.

In this group of 49 persons there were 31 females and 18 males. This difference in sex incidence was most evident in the North Carolina Baptist Hospital group, in which 15 of the 20 cases occurred in females. The ages of the patients ranged from 9 to 80 years, most of the cases being fairly well distributed among those between the ages of 20 and 70.

The clinical picture of bromide intoxication has been described repeatedly but is still not widely recognized. Hanes and Yates² emphasized the importance of recognizing the early symptoms of headache, diminished power of concentration and nervousness. They pointed out the similarity of these mild toxic symptoms to those of the common psychoneuroses and the danger of the physician prescribing increased bromide to combat these symptoms, thus precipitating the more severe forms of intoxication.

The outstanding signs and symptoms recorded in the histories of the 49 cases reported here are, in order of frequency, (1) mental confusion, (2) stupor, (3) delusions, (4) headache, (5) hallucinations, (6) nervousness, (7) weakness, (8) disturbances in gait, (9) brown furry coating of the tongue, (10) palpitation, (11) slurring of speech, (12) irritability, (13) depression or elation, (14) insomnia, (15) "smothering spells," (16) "dizziness," (17) anorexia, (18) nausea and

This low incidence of cutaneous eruptions is in agreement with the findings of most recent observers, who have pointed out that the occurrence of skin rash in bromism is not common and has been overemphasized in the past. There is no relationship between blood bromide level and cutaneous manifestations. De Gowing³

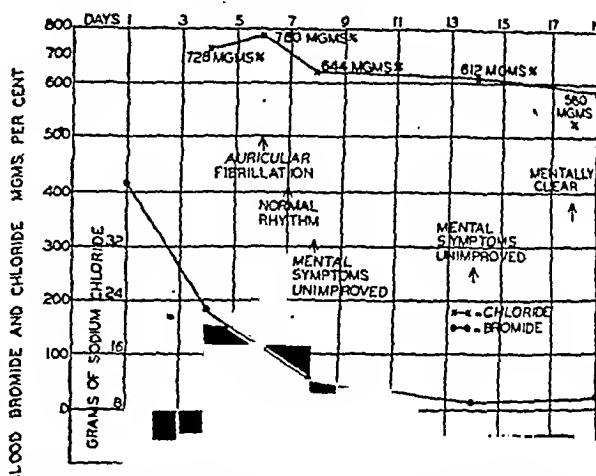

Chart 1 (M. D.).—Demonstration of the slow response in mental symptoms as contrasted with the prompt fall in blood bromide. An attack of paroxysmal auricular fibrillation occurred during the period of intensive sodium chloride therapy (20 to 30 Gm. daily).

cites the unpublished work of Kimberly, who concluded that the cutaneous manifestations that occasionally occur are due to idiosyncrasy rather than to the toxic effect of the drug. The low incidence of cutaneous manifestations would support this view.

Sixteen patients exhibited low grade elevations in temperature which disappeared after adequate treatment of the bromism. One patient, who was severely intoxicated, was confused and irrational and had considerable fever, varying between 39 and 40 C. (102.2-104 F.) for ten days. In addition, rigidity of the neck and a positive Kernig's sign made the diagnosis of meningitis likely. However, lumbar puncture revealed a normal spinal fluid under normal pressure. The spinal fluid contained 90 mg. per hundred cubic centimeters of bromide and the blood bromide level was 150 mg. per hundred cubic centimeters. The fever subsided and the meningeal signs slowly disappeared under treatment for the bromide poisoning.

In this series of cases there was no instance of bromism superimposed on an underlying major psychosis. In mental institutions, however, the incidence of bromism in such cases is quite high. Wagner and Bunbury⁴ reported that in 1,000 routine admissions to the Colorado Psychopathic Hospital 77 patients showed appreciable amounts of bromide in the serum. In 44 of these the mental symptoms were caused or aggravated by the bromide. Garrard⁵ found a blood bromide level above 50 mg. per hundred cubic centimeters in 27.5 per cent of 1,042 patients admitted consecutively to the North Carolina State Hospital for the Insane at Morganton over an eighteen months period of time. More than 4 per cent of the patients admitted had a blood bromide level above 150 mg. per hundred cubic centimeters, which the author considers the toxic level.

Anorexia.....	1

vomiting, (19) transitory visual disturbance and (20) transitory incontinence (table 1).

A skin rash was noted in only 5 of the 49 cases. In 2 cases the rash was acneiform in character; in 1 the appearance was typical of erythema nodosum. The eruptions were not adequately described in 2 cases. In 2 other instances vague indefinite skin lesions were noted but were not believed to be related to the bromism.

2. Hanes, F. M., and Yates, Anne: An Analysis of 407 Instances of Chronic Bromide Intoxication, *South. M. J.* 31:667 (June) 1939.

One of our patients (chart 1) had been committed to a state mental institution when members of his family brought him to the North Carolina Baptist Hospital for observation before assigning him to an institution for the insane. This patient's wife, incidentally, was in the hospital at that time suffering from an identical condition (chart 2). After having brought his wife to the hospital two weeks previously, he had returned home and had consumed what remained of a pint of salty medicine (sodium bromide) that had been prescribed for his wife and had been the cause of her illness. After adequate treatment for the bromide poisoning both patients left the hospital completely well.

It is unfortunate that patients are so frequently marked by the stigma that goes with admission to a mental institution, because of bromism, a condition that may be easily suspected from the clinical picture, readily confirmed by examination of the blood and adequately corrected by simple therapy. Actually the disease should not exist, for it is entirely preventable by the observance of a few simple rules guiding the use of bromide-containing medications.

DISEASES ASSOCIATED WITH BROMISM

The most common associated and underlying diseases in this series were (1) functional nervous system disorders (anxiety state, neurasthenia, hysteria), (2) generalized arteriosclerosis, (3) cerebral arteriosclerosis, (4) heart disease, (5) malnutrition and avitaminosis, and (6) other drug intoxications, including acetanilid, phenobarbital and sulfonamide poisoning (table 2).

Aside from the high incidence of bromism in psychoneurotic and emotionally unstable patients, the condition occurs with some regularity in patients with certain other disorders. Patients with generalized arteriosclerosis and especially those with cerebral arteriosclerosis appear to be unusually susceptible to bromide intoxication. Anemia may often be a contributing factor, as was pointed out by Gundry.⁶ In patients suffering from these conditions smaller amounts of bro-

person a blood level of 150 mg. per hundred cubic centimeters is often associated with few or no symptoms, whereas in some patients with cerebral arteriosclerosis, malnutrition or anemia a blood level as low as 75 mg. per hundred cubic centimeters may be associated with the signs of severe intoxication.

Nine patients in this series of cases exhibited the signs and symptoms of heart disease. Seven of the 9 had hypertensive cardiovascular disease, 1 had arteriosclerotic heart disease and 1 had severe cor pulmonale secondary to long standing bronchial asthma. The degree of intoxication in these patients varied from very mild to severe and roughly paralleled the height of the blood bromide levels. In all of the severe cases the blood level was 200 mg. per hundred cubic centimeters or higher. The efficiency of cardiac function in these patients varied from a slight disturbance to serious impairment with severe heart failure. There was no apparent relationship between the degree of heart failure and the severity of bromide intoxication. From this small series of cases it would appear therefore that, while bromide poisoning occurs rather frequently in patients who have heart disease, the heart disease does not in itself predispose such patients to bromide intoxication. It seems more likely that the presence of heart disease acts primarily as a factor in precipitating an anxiety state and that the bromides are taken or prescribed because of the latter condition.

The coexistence of heart failure and bromide poisoning presents a therapeutic problem of considerable importance, for in the treatment of one sodium chloride is withheld and in the treatment of the other the ingestion of sodium chloride is forced. No patient with heart failure who is being treated with a salt free or salt poor diet should be given bromides, and all such patients should be warned of the danger of using the various "patented" bromide containing remedies. When bromide poisoning exists in a patient with heart failure one may substitute ammonium chloride for sodium chloride, thus supplying the chloride need in

Chart 2 (R. D.).—Again illustrating the slow improvement in the mental symptoms and the prompt fall in the blood bromide level following intensive sodium chloride therapy.

mide and lower blood bromide levels are required to produce the symptoms of bromism. For this reason it is impossible to set a fixed blood bromide level above which the symptoms of intoxication always appear and below which they are absent. In an otherwise healthy

6. Gundry, L. P.: Bromide Intoxication: Report of 15 Cases, J. A. M. A. 113: 466 (Aug. 5) 1939.

the treatment of bromism and eliminating the sodium, the element that needs be withheld in the treatment of heart failure and edema.

TREATMENT

Fortunately the treatment of bromism is simple and effective. It consists in the administration of sodium chloride and the forcing of fluids to hasten the elimination of bromide. It is important to point out, however, that response to therapy, especially when the degree of intoxication is severe, is slow and rarely dramatic. Almost always the blood bromide level falls before there is any appreciable change in the patient's mental state. When the blood level is 250 mg. per hundred cubic centimeters or above there is usually a drop to 100 mg. per hundred cubic centimeters or less within five to seven days after the institution of adequate treatment. Improvement in mental symptoms, however, may lag far behind. This is illustrated by charts 1 and 2, in which it can be seen that, in spite of the prompt fall in blood bromide levels, nineteen days elapsed after the beginning of treatment before the patients became mentally clear.

Chart 3 (T. P.).—Illustrating the steady and continuous fall in blood bromide level and clearance of mental symptoms of a patient receiving 6 to 8 Gm. of sodium chloride daily.

It is important to recognize this delay in the response of mental symptoms to treatment when the question arises, as it frequently does, as to whether the patient is suffering from an underlying major psychosis. The blood bromide level is of little aid in the evaluation of mental symptoms after treatment is begun. It becomes simply a matter of time and observation, and one is not justified in ascribing persisting mental symptoms to some condition other than bromism until at least three weeks have elapsed after the beginning of treatment. The reason for this persistence of the mental symptoms is unknown. The bromide ion exerts its pharmacologic effects through its presence in the extracellular fluids of the body, and the nervous system seems to be unusually sensitive to the substitution of bromide for chloride.⁷ The ratio of bromide to chloride in the extracellular fluids of the body everywhere is the same as that in the serum, except in the brain and cerebrospinal fluid, where the ratio is lower.⁸ It may be that the equilibrium between the blood and the

extracellular fluids of the nervous system occurs more slowly, thus accounting for the difference in the ratio between bromide and chloride ions. If this is true, then the slow improvement of the mental symptoms as contrasted with the prompt fall in the blood bromide level may be accounted for. Equilibrium between serum and brain and cerebrospinal fluid being slowly established, the substitution of chloride for bromide in the nervous system may occur much less rapidly than it does in the serum. Thus, while bromide is rapidly eliminated from the serum, it is slowly displaced in the nervous system and continues to exert its effect there.

Six to 8 Gm. of sodium chloride daily would appear to be the optimum dosage. Larger amounts, 15 to 30 Gm., may be given with somewhat more rapid fall in the blood bromide level, but to little advantage since increasing the salt dosage does not hasten the removal of the mental symptoms and has the disadvantage of causing nausea, vomiting and diarrhea. Such manifestations of too rapid administration of sodium chloride are not only unpleasant but may actually retard recovery because much needed fluid is lost by the vomiting and diarrhea and also because the sodium chloride intake cannot be adequately controlled. In 1 case (chart 1) a paroxysm of auricular fibrillation occurred during the period of intensive salt therapy.

When 6 to 8 Gm. of sodium chloride is given daily by mouth or parenterally, if necessary, the undesirable gastrointestinal side effects are usually avoided, and, while somewhat less abrupt, the fall in blood bromide level begins promptly and is steady and continuous (chart 3). Furthermore, the improvement in mental status seems to occur just as rapidly as when larger amounts of sodium chloride are given.

SUMMARY

Bromide poisoning has continued to be a common condition in spite of numerous clear expositions of its cause, prevention and treatment in the past fifteen years. Forty-nine additional cases have been observed.

More than 50 per cent of the cases in this series were referable to the injudicious use of bromides by practicing physicians and their failure to recognize the toxic effects, once they appeared. Other causes were the result of the uncontrolled sale of "patented" pain remedies containing bromide.

Mental symptoms due to bromide poisoning often respond much more slowly to treatment than does the level of bromide in the blood.

Paracelsus.—Paracelsus (1493-1541) was an original, although eccentric, figure, who is sometimes called the father of chemistry and the reformer of materia medica. He was born in Einsiedeln, near Zurich, Switzerland. He claimed to have traveled all over the world. He taught as professor of medicine in Basle and in other cities. His bombastic method of delivery, the license of his criticism of orthodox doctors, his theatrical tricks—such as publicly burning the works of Galen and Avicenna—led to his continual persecution, and he wandered from place to place in Germany, finally dying in Salzburg. Tradition says that he believed in, in fact owned, the philosopher's stone. His mind, his philosophy, looked back to the Middle Ages and forward to the Renaissance. He introduced mineral baths; he also introduced laudanum, mercury, lead, arsenic, iron, copper sulfate, tinctures and alcoholic extracts into the pharmacopoeia. He discarded and ridiculed the doctrine of the four humors. His principal works are *Chirurgia magna* (1536), *De gradibus* (1568), *A Treatise on Diseases of Miners* (1567).—Clendening, Logan: *Source Book of Medical History*, New York, Paul B. Hoeber, Inc., 1942.

TOXIC REACTIONS OF SULFAGUANIDINE THERAPY

CAPTAIN JOHN J. BUNTING

AND

CAPTAIN NORMAN E. LEVAN

MEDICAL CORPS, ARMY OF THE UNITED STATES

In the course of sulfaguanidine therapy of ambulatory patients a significant number of complications were noted, which it is our purpose to report in this paper. The patients treated were 191 soldiers on a tropical isle. At the time of treatment they were either convalescent or contact carriers of *Shigella dysenteriae flexner*, W type. By "convalescent carriers" is meant those whose stool cultures, following complete symptomatic recovery from the acute stage of the disease, were found to be positive for the causal organism; the term "contact carriers" is applied to persons who at no time had any acute symptoms but whose stool cultures were positive.

In addition to a fairly large group, some 20 per cent, with subjective complaints, 22 patients (11.5 per cent) in this series developed objective reactions of sufficient severity to necessitate discontinuing sulfaguanidine. No evident correlation was found to exist between previous sulfaguanidine treatment and reactions. Eight (36.4 per cent) of the 22 patients with reactions had had previous therapy, as compared with 76 (40 per cent) of the entire group of 191. These 76 had received the drug earlier, in amounts up to 100 Gm, during their acute stage of dysentery.

Various considerations necessitated the division of patients into two groups, each of which was managed by one of us. The essentials of treatment in the two groups were the same, a ten day course of sulfaguanidine 3.5 Gm. three times daily for a total contemplated dosage of 105 Gm. Patients were on a "duty" status throughout, although light duty was recommended when possible. Limited laboratory facilities made it impossible, unfortunately, to obtain determinations of sulfaguanidine levels in the blood or stools. In one group of 83 cases blood counts and urinalyses were done at two to three day intervals, more frequently where complications were noted or suspected. In the other 108 cases blood counts and urinalyses were done only when reactions occurred, but care was taken to insure a urinary excretion of at least 1,500 cc. daily. No abnormalities in the blood picture were noted in any patient. Results in the two groups were closely parallel.

Febrile reactions, with oral temperatures ranging from 100 to 103.8 F., were noted in 18 cases. 9.4 per cent of the total treated. This complication appeared on the third to the fifth day of therapy in 11 cases. In 10 of the 18 no previous sulfaguanidine therapy had been given. On withdrawal of the drug the temperature returned to normal within twenty-four hours in all instances. In order to obtain confirmation that the drug was responsible for the pyrexia, 7 patients were then given additional sulfaguanidine. All became febrile within four to eight hours. In 2 instances a third similar trial produced the same results.

Five patients developed dermatologic reactions during the course of treatment. Three of these were urticarial, 2 scarlatiniform. All 5 cleared completely within twenty-four hours of cessation of sulfaguanidine.

The most frequent finding was that of intermittent crystalluria, noted in 22 (26.5 per cent) of the 83 cases in which repeated urinalyses were done during the course of treatment. In only 3 cases was this finding associated with the febrile reaction. It was observed as early as the second day of sulfaguanidine therapy in 2 instances, on the third day in 4 others, and it persisted throughout the ten day course in 5 cases. Transient hematuria occurred in 4 instances, in 1 of which there was diminution of urinary output for a twenty-four hour period preceding the appearance of the crystals. In all other instances the crystalluria was attended by no other signs or symptoms referable to the genitourinary tract. The crystals were large and rectangular and were present in both alkaline and acid specimens.

One or more of the subjective symptoms headache, mild malaise, anorexia, occasional backache and nausea, in order of frequency, was complained of by approximately 20 per cent of the patients.

REPORT OF CASES

CASE 1.—A soldier aged 24 received a total of 21 Gm. of sulfaguanidine in forty-eight hours, at the end of which time he had a rise in temperature to 103 F. with chills, nausea and severe headache. The drug was discontinued, and within twenty-four hours the temperature had returned to normal and the subjective complaints disappeared. Two days later, following an additional 3.5 Gm. of sulfaguanidine, the fever returned, again subsiding on cessation of the drug. The blood count and urinalysis were normal at that time.

CASE 2.—A soldier aged 25, on the eighth day of treatment, at which time he had received a total of 84 Gm., developed a temperature of 102.8 F., slight chills and severe headache. The drug was discontinued, with a subsequent prompt fall in temperature to normal. Blood count and urinalysis were normal.

CASE 3.—A soldier aged 19 had received a total of 32 Gm. while hospitalized, with no reaction. Two weeks later a course of sulfaguanidine was begun on an outpatient status, and on the fourth day of treatment, at which time 35 more grams had been given, the patient developed fever of 102 F. and complained of severe headache. The blood count and urinalysis were normal. The drug was discontinued, the temperature returned to normal, and symptoms subsided within twenty-four hours.

CASE 4.—A soldier aged 22 received a total of 96 Gm. while hospitalized, with no reaction noted. Two weeks later, after receiving 28 more grams of sulfaguanidine in a three day period, the temperature rose to 101.8 F., with complaints of severe headache, nausea and chills. On cessation of therapy all signs and symptoms returned to normal. Blood count and urinalysis were normal.

CASE 5.—A soldier aged 28 received a total of 48 Gm. during hospitalization with no reactions noted. Two weeks later, after receiving 28 Gm. within three days, the temperature rose to 102.2 F., with complaint of headache. The drug was discontinued, and fever and headache disappeared within twenty-four hours. Blood count and urinalysis were normal.

CASE 6.—A soldier aged 24, after receiving 28 Gm. of sulfaguanidine in three days, developed fever of 102.4 F., chills, headache and nausea. The drug was discontinued. Prompt fall in temperature and disappearance of subjective complaints followed within twenty-four hours. Forty-eight hours later the patient was given 7 Gm. of sulfaguanidine, with return of fever and subjective symptoms. Recovery to normal again followed withdrawal of the drug. The blood count and urinalysis were normal.

CASE 7.—A soldier aged 26, on the third day of treatment following a total of 27 Gm., developed fever of 103.2 F., severe headache, backache, nausea, anorexia and chills. The drug

was discontinued, and all symptoms and fever disappeared within twenty-four hours. Two days later 3.5 Gm. of sulfaguanidine was given; fever of 102.4 F., headache and nausea returned. Recovery again followed withdrawal of the drug. Blood count and urinalysis were normal.

CASE 8.—A soldier aged 37, after receiving a total of 35 Gm. of sulfaguanidine in four days, developed fever of 101.4 F., chills and headache, all of which cleared up within twenty-four hours when the drug was stopped. Blood count and urinalysis were normal.

CASE 9.—A soldier aged 37, on the third day of treatment, after receiving 28 Gm. of sulfaguanidine, developed a fever of 102.6 F., malaise, anorexia and nausea. The drug was discontinued, with prompt return to normal within twenty-four hours. Blood count and urinalysis were normal.

CASE 10.—A soldier aged 23 had received a total of 100 Gm. of sulfaguanidine during hospitalization with no ill effects reported. Two weeks later, following administration of 42 more grams in four days, the patient developed a fever of 101.2 F., slight headache and malaise. The fever and other complaints disappeared within twenty-four hours when the drug was discontinued. Blood count and urinalysis were normal.

CASE 11.—A soldier aged 20 had received a total of 64 Gm. during hospitalization, with no ill effects reported. Two weeks later, after an additional 63 Gm. in six days, the patient developed a generalized scarlatiniform eruption of the trunk and extremities. The patient had had no previous skin eruptions. No associated subjective symptoms were present. The rash disappeared within forty-eight hours of withdrawal of the drug and did not recur. The blood count and urinalysis were normal.

CASE 12.—A soldier aged 24, after receiving 73.5 Gm. of sulfaguanidine, on the seventh day of treatment developed a temperature of 101.6 F., chills and malaise. Return to normal followed within twenty-four hours of withdrawal of the drug. Thirty-six hours later two additional doses, 7 Gm., elicited a temperature rise to 101.4 F. The drug was again discontinued, with a prompt return to normal. Except for moderate crystalluria on two occasions, blood counts and urinalyses were normal.

CASE 13.—A soldier aged 26 developed headache and malaise on the fourth day of treatment and slight chills on the eighth day. On the tenth day, at which time he had received a total of 101.5 Gm., he experienced severe headache, malaise, anorexia and fever of 103.8 F. All symptoms subsided and temperature returned to normal in less than twenty-four hours. Blood counts and urinalyses were normal.

CASE 14.—A soldier aged 27 had received a total of 30 Gm. while hospitalized, with no toxic reaction. Seven days later drug treatment was reinstituted. On the fifth day of treatment, at which time he had received 49 Gm., he developed a temperature of 101.8 F., which subsided within twenty-four hours. A day later 7 more grams was given, with a prompt rise in temperature to 103 F. The fever again subsided on discontinuance of the drug. Blood counts and urinalyses were normal.

CASE 15.—A soldier aged 27 had received 32 Gm. of sulfaguanidine during a previous period of hospitalization, with no toxic manifestations. Two weeks later further treatment was given, and, after receiving 73.5 Gm., on the seventh day of therapy, his temperature rose to 103.4 F., with pronounced malaise. On discontinuance of the drug, fever and discomfort ceased. After two days 17.5 more grams was given, with a resultant urticaria of the eyelids, lips, hands, back and legs, which subsided within twenty-four hours.

CASE 16.—A soldier aged 20, after receiving 63 Gm. of sulfaguanidine in six days, developed fever of 101.2 F. and severe backache. Moderately decreased urinary output had been noted in the preceding twenty-four hours. Urinalysis showed occasional red blood cells and moderate crystalluria.

All findings disappeared within a day following withdrawal of the drug. The blood counts were normal.

CASE 17.—A soldier aged 20 received a total of 96 Gm. during a previous period of hospitalization. At that time he had complained of malaise, anorexia and emesis on two occasions but developed no other symptoms referable to the medication. Eight days later sulfaguanidine was again started. After receiving only 10.5 Gm. he developed fever of 102.4 F. and severe malaise. Return to normal took place within eighteen hours of cessation of medication. An additional 7 grams two days later again caused a rise in temperature to 99.8 F. and a moderate urticaria of the chest and arms. Both fever and urticaria promptly subsided. A third rise in temperature to 100 F. followed administration of 7 Gm. of sulfaguanidine forty-eight hours later, with the usual return to normal after cessation of treatment. Urinalyses and blood counts were normal throughout.

CASE 18.—A soldier aged 22 developed crystalluria on the fourth day of therapy, at which time he had received 42 Gm. Moderate hematuria was noted on the seventh day of therapy, as well as persistent crystalluria. Blood counts were normal.

CASE 19.—A soldier aged 24 had received a total of 48 Gm. during previous hospitalization without toxic effects. Two weeks later he was again placed on sulfaguanidine, and, after receiving 84 Gm., on the eighth day of treatment developed an urticaria of the wrists and forehead, which disappeared on discontinuance of the drug. Blood counts and urinalyses were normal.

CASE 20.—A soldier aged 32 complained of severe headache, malaise and anorexia from the second day of therapy. In addition, crystalluria was noted at that time. All these findings persisted throughout the course of therapy, which was terminated on the ninth day because of a rise in temperature to 100 F. All complaints then disappeared promptly.

CASE 21.—A soldier aged 21 developed crystalluria on the eighth day of treatment, at which time he had received 77 Gm. The following day the presence of red blood cells in the urine in addition to the crystals necessitated cessation of therapy. The condition disappeared in forty-eight hours. The blood counts were normal throughout.

CASE 22.—A soldier aged 29 developed a scarlatiniform eruption of the trunk and extremities, crystalluria, moderate hematuria and temperature of 101.4 F. on the tenth day of treatment, at which time he had received a total of 98 Gm. of sulfaguanidine. The rash, fever and crystalluria disappeared within twenty-four hours; the hematuria persisted an additional day.

SUMMARY

1. Sulfaguanidine was given to 191 ambulatory carriers of bacillary dysentery in evident good health. Twenty-two (11.5 per cent) developed complications of sufficient severity to necessitate discontinuing the drug.

2. Febrile reactions occurred in 18 patients (9.4 per cent), dermatologic reactions in 5 (2.6 per cent) and hematuria in 4 (2.1 per cent).

3. Crystalluria was noted in 22 (26.5 per cent) of 83 cases in which repeated urinalyses were done. This finding, when it existed without concomitant complications, was not considered sufficient indication for discontinuing the drug.

4. The factor of increased fluid loss due to perspiration in the soldiers receiving the drug, as they were on a duty status in a tropical climate, is felt to be at least a contributing condition in development of reactions of the severity and frequency reported herein.

5. From these observations, it is evident that sulfaguanidine therapy is not without its dangers, and the same caution in administration should be exercised as with the other sulfonamides.

DIAGNOSIS OF LIVER ABSCESS
BY MEANS OF THOROTRAST
HEPATOSPLENOGRAPHY

WALLACE M. YATER, M.D.

WASHINGTON, D. C.

From now on we must expect a great increase of amebiasis in the United States as our soldiers and sailors return home from the various theaters of war. We must be alert to the possibility of this disease not only in cases of diarrhea but in cases of vague abdominal complaint and fever not readily explained, since many of our boys may be victims of chronic amebiasis or may act as carriers. Cognizance must be taken also of the fact that amebic liver abscess may not develop until years after the primary intestinal infection has become asymptomatic, as illustrated by some of my cases.

The diagnosis of liver abscess, either amebic or pyogenic, is often difficult. It should be suspected in every case of discomfort in the right upper quadrant of the abdomen with fever, either with or without enlargement of the liver. In some cases there may be fever and enlargement of the liver without pain. In many cases there is little or no jaundice. Chills are more common in the pyogenic form. The presence of a rounded protuberance of the liver is more frequent with the amebic form, but this manifestation may not be evident on physical examination, since the swelling may be above the costal margin.

There is no better way of making the diagnosis of either form of liver abscess than Thorotrast hepatosplenography, a procedure which I have employed for nearly thirteen years in several hundreds of cases. A follow-up study¹ of 286 patients so examined over the first ten year period of my use of this procedure revealed no evidence of harmful effects from the presence of thorium dioxide in the tissues in the amounts used. It was noted that liver abscess was one of the conditions in which the method was most valuable as a diagnostic procedure.

Thorotrast hepatosplenography was developed both by Oka and by Radt in 1929 and makes use of roentgenographic examination of the liver and spleen following the intravenous administration of a stabilized colloidal solution of thorium dioxide.²

When this material is introduced into the blood stream it is rapidly removed and engulfed by the cells of the reticuloendothelial system. Since the liver and spleen contain these cells in greatest concentration, these organs will receive the greatest amount of Thorotrast. By virtue of its high molecular weight, thorium dioxide is radiopaque and thus serves as a contrast medium. In a Thorotrast hepatosplenogram normal liver tissue appears of a homogeneous density about equal to that of the vertebrae, the spleen about the same density as the ribs. Since a liver abscess is a circumscribed area of pus containing necrotic hepatic tissue and is devoid of active reticuloendothelial cells, it will contain none of the Thorotrast and will be of lesser density than surrounding normal liver tissue on the x-ray film. In this manner liver abscess, especially the solitary amebic variety, is easily demonstrated and precisely located. The only lesions that need be differentiated are neo-

plasm and cyst. Metastatic carcinoma appears as areas of lesser opacity with clearcut margins and often with a halo of condensed liver tissue. Solitary tumors are rare but present roentgenographic features similar to those of metastatic growths. The same is true of echinococcic and other rare cysts. The outline of a solitary liver abscess may or may not be rather sharp but in any case does not have a halo of increased density. Multiple pyemic abscesses are smaller and present a fuzzy outline that blends with the adjacent liver parenchyma.

The method now employed is to inject slowly intravenously 75 cc. of Thorotrast (adult dose) and to make the x-ray exposures several hours later. Studies of the rate of deposition of Thorotrast³ have shown that most of it is removed from the blood stream during the first fifteen minutes following injection and that after two hours the films made are as good as at any time thereafter.

In making the injection it is important to avoid infiltration of the subcutaneous tissue, since Thorotrast remains there and in time produces unsightly hard nodules which may become painful and require excision. These foreign body tumors do not become malignant in man.⁴ To simplify injection the Thorotrast may be diluted with several hundred cubic centimeters of isotonic solution of sodium chloride and be given by the gravity method. In this way one can ascertain that the needle is entirely within the vein before the Thorotrast is added to the flask. Mild reactions are not uncommon when the whole 75 cc. is injected at one time. They are so unimportant, however, that the old method of injecting 25 cc. on each of three successive days was abandoned in order to save time. Good films are usually obtainable with the patient placed in the prone position by means of the following technic: 300 milliamperes, kilovolt peak 58, distance 40 inches, time $\frac{1}{4}$ to $\frac{1}{2}$ second, depending on the size of the patient.

Five cases of probable amebic liver abscess and 2 cases of pyogenic abscesses will be described briefly. Four of the solitary abscesses have been reported previously,⁵ and these will be reviewed in less detail.

AMEBIC LIVER ABSCESS

CASE 1.—A white man aged 38 entered Georgetown University Hospital on July 24, 1936 stating that he had had severe pain in the right upper quadrant of the abdomen intermittently and that for six weeks he had had fever. The pain was sharp and stabbing in the hepatic area, and there was a dull constant ache in the right posterior lumbar region. Intermittent vomiting had occurred, and a loss of 40 pounds (18 Kg.) had resulted. There had been a chill the day before admission. Bowel function had not been abnormal. The patient appeared seriously ill but was not jaundiced. The temperature was 101 F. and the pulse rate 100. There was hepatomegaly with pronounced tenderness over the right lobe, the edge of which was rounded and extended 6 cm. below the right costal margin. A definite hypochromic anemia with a high granulocytic leukocytosis was found. Repeated stool examinations were normal. A moderately severe, irregular fever persisted, ranging from 98 to 103 F. Troublesome bronchitis developed. A hepatosplenogram revealed an area of decreased density in the lower portion of the right lobe of the liver indicating the presence of an abscess. Drainage of thick, reddish brown pus was instituted, and the patient was

discharged as cured on the fortieth day after operation. Although amebas could not be found, a course of emetine hydrochloride was given.

CASE 2.—A white man aged 36, who entered Georgetown University Hospital on Feb. 22, 1938, had been ill for nine weeks with nausea, vomiting, diarrhea and fever. He was seriously ill, emaciated and cachectic but not jaundiced. The right lobe of the liver seemed to be considerably enlarged, and there was dullness posteriorly above the right diaphragmatic area. The leukocyte count was normal, but there was severe anemia. Repeated stool examinations were negative. A moderate, irregular fever continued, with remissions of several days at a time. The diarrhea was replaced by constipation with abdominal distention. The first hepatosplenogram was unsatisfactory but showed the liver to be greatly enlarged. Aspiration of the liver was productive of 100 cc. of brownish fluid. An additional 25 cc. of Thorotrast (making a total of 100 cc.) was injected, and the hepatosplenogram revealed a large area of decreased density involving the upper two thirds of the liver. The next day paracentesis of this area resulted in the withdrawal of 1,750 cc. of purulent fluid, which at first was dark brown, with clumps of necrotic debris and later was light yellow and thick. Two days later the liver was exposed surgically and 3 liters of pus was evacuated through an aspirator. Four days later 1,200 cc. of purulent fluid was aspirated from the right pleural cavity, and cultures revealed *Staphylococcus aureus*. The same day the patient died. Amebas had not been found, but the case was probably one of amebiasis with complicating staphylococcal empyema.

CASE 3.—A white man aged 41, who had resided in the Philippines from 1925 to 1931 and during that time had had an illness of several weeks' duration characterized by fever and diarrhea, three months before admission to Georgetown University Hospital on Oct. 23, 1941 had developed an intermittent dull, aching pain in the right upper quadrant of the abdomen and in the lower half of the right side of the chest, associated with a low grade afternoon fever, anorexia and a loss of 67 pounds (30 Kg.). The bowels were constipated. He was greatly debilitated on admission, and his temperature was 102 F. and his pulse rate 90 per minute. The base of the right lung was dull to percussion and the breath sounds were absent.

Fig. 1 (case 3).—Large amebic abscess in middle of right lobe of liver before operation.

It appeared that the right hemidiaphragm was elevated. The liver was not palpable. There was moderately severe anemia, and the leukocytes numbered 13,500, with 87 per cent neutrophilic granulocytes. Repeated stool examinations were negative. The temperature continued to be elevated with afternoon rises to 101 to 102 F. Hepatosplenograms made on November 12 revealed an area of decreased density, 15 cm. in diameter, occupying the middle of the liver (fig. 1) which, together with

the clinical findings, definitely established the diagnosis of solitary liver abscess. The abscess was drained, and a course of emetine hydrochloride was given, followed by a course of chiniofon. On the fourth day postoperative transient diarrhea developed, and *Endamoeba histolytica* was demonstrated in the stools. The "anchovy sauce" pus from the hepatic abscess

Fig. 2 (case 4).—Large abscess in upper half of right lobe before rupture into right lung.

did not show amebas, as is usual. Steady improvement followed the second stage of the operation, and the patient was discharged on December 13 as cured.

CASE 4.—Three months before admission to Georgetown University Hospital on Feb. 26, 1942 a white man aged 47, residing in Florida, had had an illness characterized by chills, fever, sweating and diarrhea. He was treated with sulfathiazole, and after ten days his temperature became normal and the diarrhea subsided for two weeks but then recurred. A weight loss of 30 pounds (13.6 Kg.) resulted. There was no abdominal pain or jaundice. Findings on admission included the presence of a large, hard, immovable mass about 5 cm. in diameter on the posterior wall of the left hemithorax in the region of the seventh rib, evidence of elevation of the right hemidiaphragm with limited motion, and some tenderness of the edge of the liver, which was palpable 2 cm. below the right costal margin. There was moderate anemia and a leukocytosis of 19,200 with 73 per cent neutrophilic granulocytes. Repeated stool examinations were negative. A remittent fever ranging up to 103 F. persisted. Hepatosplenograms showed a slightly enlarged liver with elevation of the right hemidiaphragm, and a large area of decreased density in the upper half of the right lobe of the liver of rounded contour (fig. 2). The swelling of the left hemithorax was shown to be an osteochondroma. Signs of fluid in the right pleural cavity appeared, and during the night preceding planned operation for liver abscess the patient began to expectorate a large amount of thick, brick red, foul smelling fluid resembling anchovy sauce (fig. 3). Operation was canceled, but aspiration of 400 cc. of similar pus was aspirated from the liver through a cannula. Amebas were not found in the pus. After a week of coughing the temperature became normal and improvement rapid. The patient was discharged as cured on March 26. During hospitalization he received a course of emetine hydrochloride followed by a course of chiniofon.

CASE 5.—J. H. R., a white man aged 39, entered Gallinger Municipal Hospital on Sept. 8, 1943 after two weeks of productive cough and morning vomiting and three days of fever and pain in the right upper quadrant of the abdomen. He

had observed a swelling the size of a plum beneath the right costal margin. This swelling was noted on admission to the surgical service, but on the second hospital day both swelling and pain disappeared. Bowel function and temperature were normal. He remained in the surgical service for two weeks. Roentgenographic examinations of the chest, gallbladder and gastrointestinal tract were normal. Four days after discharge the pain and swelling recurred, and after a week of suffering he was readmitted, this time to the medical service. The patient had been raised in the mountains of West Virginia. The only illnesses he remembered were an attack of "intestinal flu" at 12 and mumps at 15.

The patient was poorly nourished and pale, with scattered, coarse bronchial rales and a tender mass the size of a lemon just below the right costal margin. There was some muscle spasm and warmth and erythema overlying the mass. A fever ranging between 100 and 101 F. was present, and the leukocyte count was 16,200, with a normal differential count. A flat x-ray film of the abdomen, films of the spine and pyelograms were normal. A hepatosplenogram showed a rounded opacity measuring 5 by 10 cm. in the lower portion of the right lobe of the liver (fig. 4), which was interpreted as a solitary liver

Fig 3 (case 4).—Hepatosplenogram made the day after rupture of abscess into right lung.

abscess. On the same day both cystic and motile forms of *Endamoeba histolytica* were found in the stools.

Because the pain and tenderness were becoming rapidly more severe and because the hepatosplenogram showed a very thin rim of liver tissue under the lower margin of the defect in the liver shadow, it was felt that there was grave danger of rupture of the abscess into the peritoneal cavity. Consequently, immediate aspiration was performed through the chest wall below the pleura reflection with the needle pointing downward, and 50 cc. of purplish red, necrotic, odorless pus was easily aspirated. Three grains (0.2 Gm.) of emetine hydrochloride was instilled into the abscess cavity and along the track of the needle. The following day surgical drainage was performed through the same approach. On the same day Dr. John Bozicevich of the National Institute of Health reported that amebic complement fixation tests of the blood were the most strongly positive in his experience.

A course of emetine hydrochloride was followed after a week's rest by a course of carbarsone, which after another week's rest was followed by a course of vioform. The blood complement fixation tests gradually became negative. Recheck hepatosplenograms showed progressive decrease in the size of

the abscess cavity with almost complete obliteration on the thirty-third postoperative day (fig. 5), when the drainage tube was removed. At the time of discharge on Oct. 21, 1943 the patient had gained 15 pounds (6.8 Kg.) and stated that he had never felt better in his life. At no time during his illness had there been significant disturbance of bowel function.

Fig 4 (case 5).—Amebic abscess in lower portion of right lobe of liver before drainage.

PYOGENIC LIVER ABSCESSSES

CASE 6.—H. B., a white man aged 24, had pain in the region of the right costal margin for five weeks before admission to the hospital on Dec. 16, 1942 accompanied by night sweats and a series of three chills. The pain was increased by respiration. Vomiting had occurred twice. The patient had had

Fig 5 (case 5).—Hepatosplenogram one month after insertion of drainage tube in abscess, which has filled in, leaving evidence only of track of drainage tube.

chronic bronchitis since childhood. Physical examination showed nothing of significance except a suggestion of enlargement of the right lobe of the liver. The temperature ranged irregularly between normal and 103.8 F., with the pulse rate elevated proportionately. A rigor occurred every few days. Roentgenograms of the chest were negative. The white blood cell count was 30,300, with 86 per cent segmented neutrophils, 3 per cent

band forms and 1 juvenile leukocyte. About three weeks after admission surgical exploration of the liver revealed a firm raised area on the margin of the moderately enlarged right lobe covered by a few filmy adhesions. Aspiration was unproductive, but a biopsy revealed necrotic liver tissue infiltrated with polymorphonuclear leukocytes. A culture showed nonhemolytic streptococci and *Staphylococcus aureus*. Drainage of the hepatic lesion was fruitless and no improvement resulted. A hepatosplenogram showed a large, ill defined area in the upper portion of the right lobe of the liver which was less dense than the remainder of the liver. Another film made three weeks later showed this area more distinctly, and a third made two weeks later on was still more definite. Two weeks after the first operation the liver was again explored surgically, and several punctures were made deeply into the liver without result. However, a rubber tube was placed in one of these deep holes. From this there was a slight drainage of a watery material, and the patient seemed to improve. His appetite became good, the temperature elevation was not so great, and the white blood cell count dropped to 17,300. Three and a half weeks after the operation the patient was allowed to return home, no further chills having occurred. His condition at home remained much as it had been in the hospital, but in the early part of March chills recurred and a more toxic state set in. On March 13 the patient was brought back to the hospital, and the next day he suddenly coughed and became very dyspneic, cyanotic and apprehensive. An hour later he died.

Necropsy revealed the right lobe of the liver to be greatly enlarged and adherent anteriorly to the abdominal wall with fibrinous adhesions. In its center was a large abscess about 10 cm. in diameter filled with thick pus. A capsule was apparently forming. It appeared that one of the exploring punctures had barely missed entering the abscess. There was a right fibrinous pleuritis with an early abscess in the right lower lobe just above the diaphragm. The appendix was swollen and covered by a purulent exudate. The spleen was large and soft. Sections of the liver showed a necrotic abscess wall containing polymorphonuclear leukocytes, monocytes and fibrin. The wall of the appendix was edematous and engorged, and it contained many lymphocytes.

CASE 7.—W. R. F., a white man aged 21, entered Georgetown University Hospital on April 6, 1943 stating that since the previous morning he had had a severe, continuous pain in the region of the umbilicus. Anorexia, nausea and vomiting followed soon after. One large bowel movement had been succeeded by three loose ones containing neither mucus nor blood. The past history was irrelevant. There was abdominal tenderness but no rigidity, and rectal examination revealed tenderness on the right side at the tip of the finger. The temperature was of septic type with large remissions, from 101 to 107 F., with the pulse rate varying correspondingly. On April 9 administration of sulfadiazine was begun; two courses were given. On April 11 the blood culture was reported positive for a hemolytic streptococcus and on April 16 for an anaerobic streptococcus.

During the first week the patient complained only of a headache; the abdominal pain disappeared and was replaced by some soreness only. Symptoms of a severe bronchitis existed for a while. On April 11 jaundice of moderate degree appeared. Between April 16 and May 4 chills and sweats occurred daily. Nausea and vomiting were always troublesome. The spleen became palpable and gradually enlarged until it reached to the umbilicus. In May the liver became palpable but was never greatly enlarged. On May 9 ascites was noted and persisted. Occasional bouts of diarrhea were reported.

A hepatosplenogram made on April 26 showed nothing abnormal. However, because the history and clinical features were suggestive of suppurative pylephlebitis with liver abscesses a film was made almost weekly. One on May 11 revealed an area 5 by 7 cm. in the middle of the right lobe of the liver suggestive of an abscess. Another on May 27 showed several areas in the right lobe of the moderately enlarged liver very suggestive of multiple abscesses.

On May 21 a course of penicillin therapy was started and a total of 150,000 units given without appreciable change.

On May 28 laparotomy was performed, and an abscess was located on the under surface of the liver from which thin pus was aspirated. Although a drainage tube was inserted, this did not result in any improvement or drainage of any appreciable amount. On June 14 another hepatosplenogram still showed evidence of a group of abscesses in the liver.

The patient's course continued downhill, with various complications. He was sent home on July 1 and died there about a month later.

COMMENT

In only 2 of the first 5 cases were amebas demonstrated. However, there was no reasonable doubt that the other 3 cases were examples of amebic abscess, since the type of pus and the clinical features were consistent. It is well known that amebas cannot be recovered from the pus unless it is scraped from the wall of the abscess cavity, a procedure that from a practical standpoint is unnecessary.

Case 6 was one of pyogenic liver abscess that appeared to be solitary, but it is probable that the abscess was the result of coalescence of a number of smaller abscesses. The origin was apparently appendicitis that was unrecognized clinically. Case 7 was probably one of suppurative pylephlebitis with multiple liver abscesses from acute appendicitis that was not recognized.

This series of cases demonstrates the value of hepatosplenography in the diagnosis of both amebic and pyogenic abscesses of the liver, the former in cases in which amebiasis had not been diagnosed previously. In cases of amebic abscess the hepatosplenogram usually shows a definite, single, large abscess cavity on the first examination, whereas in cases of pyogenic abscesses repeated films made at intervals may be necessary. The clinical features of the two forms are different.

Alertness to the possibility of amebic liver abscess will be increasingly necessary as the war brings back many men from the tropics. Many of these veterans will appear to be well for varying intervals prior to the onset of symptoms caused by the abscess.

Progress in Science During the Eighteenth Century.—Equally original with the philosophers were the scientists of this period. Indeed, astronomy, mathematics, physics, chemistry, botany and physiology were enriched by a number of substantial discoveries. Newton, whose law of gravitation was expressed in a simple mathematical formula, stood supreme at the beginning of the century. His contemporary the German philosopher-mathematician Gottfried Wilhelm von Leibniz (1646-1716) evolved differential calculus. Famous also were the astronomer-mathematician Pierre-Simon Laplace (1749-1827), one of the first to study capillary action, Leonhard Euler (1707-1783) and Joseph-Louis Lagrange (1737-1813). The German astronomer-physicist Daniel Gabriel Fahrenheit (1686-1736) prepared a number of meteorological instruments and the thermometer bearing his name. A centigrade thermometer was described by the Swede Anders Celsius (1701-1744) before the Swedish Academy in 1742. Thermodynamics was greatly improved by the epochal contributions of James Watt (1736-1819), who invented the modern condensing steam engine (1769), which was a marked improvement over the clumsy apparatus of Thomas Newcomen (1663-1729). Botany obtained the status of a science by the contributions of the Swedish physician Carl von Linné (1707-1778), who laid his classification of plants on characteristics of stamens and pistils. This system was expanded by Michael Adamson (1727-1800) and by Antoine-Laurent de Jussieu (1748-1836). Georges-Louis Leclerc de Buffon (1707-1788) contributed a vast compilation on natural history in a popular and intelligent manner, which at the time of its appearance produced a tremendous sensation. —Ricci, James C.: *The Genealogy of Gynaecology*, Philadelphia, Blakiston Company, 1943.

RED BLOOD CELL PASTE IN TREATMENT OF ULCERS

AND CHRONICALLY INFECTED WOUNDS

LIEUTENANT CLIFFORD K. MURRAY
MC-V(S), U.S.N.R.

AND

CAPTAIN C. M. SHAAR (MC), U.S.N.

It has been one of the functions of the Blood and Plasma Bank of the Naval Hospital, Philadelphia, to utilize the red blood cells which are an important by-product of plasma production and which were formerly discarded. These cells have been administered with uniform success, as red cell infusions, to 663 patients suffering from anemia. A report of our results previously has appeared in the literature.¹

Moorhead and Unger² successfully used red blood cells, which were allowed to age for approximately twenty days, as a local agent in the treatment of such wounds as an open joint and an old infected burn. They suggested that this mode of therapy be given a more extensive clinical trial for better evaluation.

We applied fresh human red blood cells to a decubitus ulcer of long standing, but the problem of making these cells adhere to the wound presented itself. A sterile paste composed of concentrated red blood cells, tragacanth and hexylresorcinol was formulated. Because of the difficulty of maintaining adequate control measures in the application of this paste to open wounds, it was first decided to treat indolent ulcers which had failed to heal under the usual methods of treatment. Many of these ulcers rapidly healed. Other types of wounds—burns, deep granulating areas and the like—were thus treated. The most gratifying results were obtained in the type of lesion which fails to maintain the usual process of repair because of circulatory disorder. When the paste was applied to a dry, superficial wound it formed an impervious coating which finally became adherent to the wound, but when applied in larger quantities to deeper granulating wounds it appeared to be absorbed to some degree by the involved tissues.

PREPARATION OF THE RED CELL PASTE

The red blood cells which remain after the plasma has been aspirated (by means of a closed aseptic technique) are used for the preparation of the red blood cell paste. After the plasma is removed, the aspirating needle is plunged to the bottom of the red blood cell pack and 250 cc. of fresh type O cells are drawn over by means of a vacuum into a sterile 300 cc. dispensing bottle.

Seventy-five cc. of 1:1,000 hexylresorcinol solution is placed in a sterile pyrex glass beaker. Powdered tragacanth (2.5 Gm.) is dusted on the surface, a sterile covering applied and the mixture kept in the beaker for several hours, until a gelatinous mass forms. This is sterilized by heating in a water bath for twenty minutes at 100 C. On cooling it is removed from the

beaker with a sterile spatula and 25 Gm. introduced into the 300 cc. bottle containing 250 cc. of the sterile red cell concentrate. After thorough mixing by agitation, the paste is stored at from 2 to 5 C. while not being used. An analysis of the composition of the paste reveals 8 to 10 million erythrocytes and 2 to 3 thousand leukocytes per cubic millimeter. The hemoglobin content varies from 28 to 31 Gm. per hundred cubic centimeters.

METHOD OF APPLICATION

The wound is cleansed with isotonic solution of sodium chloride and dry gauze. The paste is then applied with sterile cotton applicators. Superficial wounds and burns are treated by applying a thin film

Fig. 1.—Varicose ulcer, right leg, two years' duration: A, Dec. 20, 1943, before treatment. B, Feb. 1, 1944, after forty-five applications of red blood cell paste. The ulcerated area has been filled in with granulation tissue, and epithelialization has taken place beneath the crust. C, February 7, one week later; crust removed. Note that the ulcer has healed. There are several small areas where crust is adherent.

of paste over the area, which is allowed to dry before being covered with a sterile dry dressing. If infection develops, the crust is removed, the wound cleansed lightly with isotonic solution of sodium chloride and a second application of the paste applied. A sterile scab soon develops, under which epithelialization takes place. In deep granulating wounds the paste is applied freely and in relatively large quantities, after which the wound is covered with a sterile dry dressing. When the wound is redressed, it is noted that a rather large quantity of the paste is absorbed by the affected tissues. The discharge decreases and the granulations take on

William R. Zeglin, Ph.M. 1/c formulated the matrix used in incorporating red cells into a paste.

a healthy appearance. After the granulations grow to the surface of the wound, a crust forms beneath which epithelium extends. The wounds are dressed either once or twice daily, depending on their condition and progress.

methods of treatment. The Kahn test was found to be negative in all of them.

In the 10 cases of varicose ulcers treated by this method, only 1 failed to heal. The duration of these ulcers was from six weeks to three years, and they

Results of Treatment of Open Wounds with Red Blood Cell Paste

Case	Type of Lesion	Duration	Previous Treatment	No. of Applications	Results
P. A.	Varicose ulcer, right leg, medial surface, 4.75 x 3 cm.	10 months (recurrent 16 years)	Hospitalization with bed rest; various ointments; Unna boots; venous ligation below knee	12	Excellent; complete epithelialization in two weeks
B. O.	Varicose ulcer, right leg, medial surface, 2 x 3 cm.	3 years	Hospitalization; sulfathiazole ointment (produced generalized maculopapular rash)	21	Excellent; complete healing in four weeks
I. V.	Varicose ulcer, right leg, lower anterior tibial region, 4 x 2.5 cm.	6 weeks	Antiseptic ointments; bed rest	11	Excellent; complete healing in twenty-six days
G. N.	Varicose ulcer, left leg, lower anterior tibial region, 4 x 2.5 cm.	3 months	High saphenous ligation; bed rest; antiseptic ointments	20	Very good; epithelialization under crust in six weeks
R. B.	Varicose ulcers, multiple, both legs	3 years	Hospitalization; sulfathiazole ointment; Unna boots; multiple injections of sclerosing agents; high venous ligation	21	Very good; complete healing; discharged six weeks after onset of treatment
R. D.	Varicose ulcer, left leg, posterior to internal malleolus, 2.5 x 2 cm.	5 months (recurrent 2 years)	Hospitalization; bed rest; antiseptic ointments	27	Very good; complete healing in six weeks
R. S.	Varicose ulcer, left leg, inferior to external malleolus, 2 x 2.25 cm.	7 weeks	Sulfathiazole powder (produced generalized dermatitis)	20	Very good; complete healing in seven weeks
G. L.	Varicose ulcer, right leg, lower medial surface, 3.5 x 2.5 cm.	2 years	Hospitalization; bed rest; various ointments; multiple injections of sclerosing agents	45	Very good; complete healing in two months (fig. 1)
M. S.	Varicose ulcer, left leg, lower medial surface, 3 x 2.5 cm.	6 weeks	Gentian violet solution	35	Fair; complete healing in ten weeks
T. M.	Varicose ulcer, left leg, lower lateral surface, 3 x 1.5 cm.	4 months (recurrent 11 years)	Ointments; multiple injections of sclerosing solutions	17	Poor; failed to respond to treatment
J. B.	Ischemic ulcers (3), left leg	1 year	Hospitalization; bed rest; various ointments	40	Very good; patient discharged in eight weeks
H. H.	Ischemic ulcers (2), left leg	2 months	Bed rest; vitamin D ointment	5	Excellent; completely healed in two weeks
A. S.	Decubitus ulcer, sacral area	3 months	Antiseptics; sulfathiazole ointment; heat applications	28	Very good; definite progressive improvement (patient died of pulmonary embolus)
J. B.	Decubitus ulcer, sacral area, 8 x 6.75 cm. (secondary to transection of cord with complete paraplegia)	8 months	Elimination of pressure in this region; sulfathiazole ointment; cod liver oil ointment; heat applications	140	Very good; completely healed (fig. 2)
S. P.	Decubitus ulcers, both buttocks, multiple, extensive (secondary to transection of cord with complete paraplegia)	1 year	Hospitalization; heat; elimination of pressure; routine treatment	41	Poor; did not respond to treatment
W. K.	Aseptic necrosis, distal phalanx, first digit, right foot (thromboangiitis obliterans)	10 months	Bilateral sympathectomy; curettage of necrotic area	3	Excellent; wound healed in eighteen days (fig. 3)
J. S.	Burns, old, 2d and 3d degree, infected, both forearms and hands	4 weeks	Petrolatum gauze; sulfanilamide powder; wet dressings of 0.25 per cent acetic acid	20	Excellent; complete epithelialization in three weeks
A. H.	Burns, old, 2d and 3d degree, infected, right anterior and posterior chest	4 weeks	Petrolatum gauze; sulfanilamide powder; normal saline compresses; split thickness skin grafts, some of which sloughed off	28	Good; progressive improvement
G. W.	Ulcer, extensive, of penis, 2.5 x 0.25 cm.; dark field negative, Frei negative, biopsy negative for carcinoma and syphilis	3 weeks	Bland antiseptics	4	Excellent; complete healing in ten days
G. C.	Amputation stump, left mid-thigh	6 weeks	Azochloramide dressings	25	Good; wound filled in with granulation tissue; epithelialization took place with exception of small area, where small split thickness graft was applied
C. H.	Ulceration, right foot, following frostbite gangrene	2 weeks	Sterile dry dressings; petrolatum gauze	7	Good; healed under crust
J. S.	Extensive crush wound, right shoulder	2 months	Petrolatum gauze; primary skin graft; sulfathiazole ointment	75	Very good; completely healed (fig. 5)
L. P.	Open granulating wound	6 weeks	Alcohol dressings; sulfathiazole powder	10	Excellent; complete healing in three weeks
C. P.	Extensive granulating wound, tibial surface, right leg, 12.5 x 7.5 cm.	4 weeks	Antiseptic dressings; split thickness graft which sloughed off	15	Very good; complete epithelialization

RESULTS OF TREATMENT

During the past fourteen months, 66 patients have been beneficially treated with human red blood cell paste and dried red blood cells. Four cases did not respond to this treatment.

The accompanying table shows the data obtained from a careful study of 24 patients treated by this method, with various lesions, such as indolent ulcers, old infected burns and extensive granulating wounds which have failed to respond favorably to the usual

varied in size from 2 by 1 cm. to 4.75 by 3 cm. Pain was quickly relieved, many patients obtaining relief after the second application of the paste. Dried red blood cells were used in other cases not included in this series, but the relief of pain was not constant. Some patients complained of a burning sensation after the lyophilized cells were applied. The inflammatory reaction which usually surrounds the varicose ulcer gradually disappeared, the granulations at the base became brighter and more healthy in appearance, and

the discharge rapidly subsided (fig. 1). Epithelization took place under a crust. When a discharge accumulated beneath the crust, the portion of the crust over this area was removed, the wound cleansed with sterile isotonic solution of sodium chloride and the paste reapplied. A thin, watery discharge may frequently appear and must be differentiated from the thick purulent discharge which, of course, is evidence of pyogenic infection.

It must be emphasized that this method is only a means to promote local healing, and other procedures, such as venous ligation and injection of sclerosing agents, should be performed when indicated.

Two cases of refractory ischemic ulcers healed under this form of treatment.

G. B. had three ulcers of the left leg which necessitated his discharge from the service. He had been hospitalized for this condition, and all the usual forms of therapy had been

Fig 2—Decubitus ulcer over sacral area in case of complete paraplegia. A, Sept 22, 1943, before application of red cell paste (note depth). B, Jan 18, 1944, after 118 applications. Area has been filled in with granulation tissues and epithelization taking place. C, April 5, area completely healed after 140 applications.

B, November 21, after third (last) application. C, December 7, twenty days after onset of treatment. Granulation tissue has filled in cavity, and epithelization has taken place in area surrounding nail bed.

applied with unsatisfactory results. These ulcers, of one year's duration, healed after forty applications of red blood cell paste, and the patient was discharged eight weeks after onset of treatment.

The paste was applied in 3 cases of decubitus ulcers which had shown no sign of progress with other methods of therapy.

J. B. had a large decubitus ulcer of eight months' duration over the sacral area, secondary to a transection of the cord caused by a gunshot wound. This type of ulcer is notoriously difficult to heal and in many cases incurable. He had previously been treated with heat, cod liver oil and sulfathiazole ointments, but progress in the healing of the lesion had not occurred. After 140 daily local applications of this paste the wound showed slow but progressive improvement, and at the present time the area is completely healed (fig. 2).

Another patient, S. P., with complete paraplegia (eighteen years' duration) and multiple extensive decubitus ulcers has failed to show any improvement with this method or any other mode of therapy.

In a case of thromboangiitis obliterans the paste was applied to a cavity which had been produced by the curettement of a necrotic area of the distal phalanx,

Fig 4—Second and third degree burns of forearm and hand. A, Oct 30, 1943, after third application of red cell paste (note crust which has formed). B, November 12, after fifteenth application of paste (epithelization is taking place beneath crust). C, after twenty five days from onset of treatment. The wound is completely healed.

Fig 5—Crush wound of right shoulder. A, before application of red blood cell paste. B, Oct 14, 1943, after seven applications. C, October 19, after twelve applications. D, after seventy five applications (wound completely healed).

first digit, right foot (fig. 3). This patient complained of severe pain which was relieved after the first application. The red blood cell paste apparently acted as

a coagulum in which granulation tissue formed. Epithelization took place under a fine crust formed by the red cell paste. This area showed complete healing in eighteen days.

Two cases of old infected burns have been treated.

J. S. suffered second and third degree burns of both forearms and hands which were treated for four weeks with petrolatum gauze, sulfanilamide powder and wet applications of 0.25 per cent acetic acid. It was planned to graft skin on the area over the dorsal surface of the left forearm after the infection subsided. However, a trial of red blood cell paste was instituted with daily applications to the raw surfaces of the wound (fig. 4). The central portion of the crust which had formed was removed frequently to allow the escape of pus, and another coat of red blood cell paste was reapplied. The discharge subsided and the burned area rapidly healed, complete epithelization taking place in three weeks. The results in this case were dramatic.

The other cases treated were open lesions of traumatic wounds with loss of substance in which the circulation was not impaired but healing was not progressing favorably (fig. 5). These cases healed satisfactorily and quickly with the red cell paste.

COMMENT

The mode of action of the red blood cell paste is undetermined. The most plausible theory is that required nutritional elements or proteins are supplied to tissue which may be deficient in these substances because of inadequate circulation. The red blood cells appear to be absorbed to a certain degree by the tissues until the granulations reach the surface and a crust forms. This crust of red blood cells apparently serves the function of protection, a source of nourishment and as a scaffolding for the support of the connective tissue. The new epithelium extends over the surface under the crust, and when the latter drops off the surface is completely covered. The red blood cells appear to stimulate the growth of granulation tissue and then act as a medium for the growth of epithelial cells over the granulating surface. This is important, since the most frequent problem in connection with an extensive granulating wound is to get the epithelium to grow over the surface.

Naide³ has successfully utilized autogenous whole blood in the treatment of ulcers and has obtained more favorable results with the use of concentrated plasma. Seldon and Young⁴ have applied dried red blood cells to open wounds with good results. In a similar manner we have used lyophilized red blood cells on a number of ulcers and granulating wounds but discontinued their routine use because severe burning pain was frequently produced at the site of the wound. However, the red blood cell paste definitely tended to relieve rather than produce pain. The powdered red cells have certain particular advantages in that they form a stable product which can be preserved indefinitely under all conditions of temperature without refrigeration, and their use is more valuable in wounds with a profuse discharge.

SUMMARY AND CONCLUSIONS

1. The method of preparation and use of human red blood cell paste for topical application that has been presented is not a panacea for chronically infected wounds but may be successfully employed in selected cases in which the slow healing is the result of local

circulatory impairment. In our group of cases it was in this type of wound that the best results were obtained. This method is not indicated in tuberculous or syphilitic ulcers.

2. Sixty-six patients with open wounds have been successfully treated with red blood cell paste and powdered red blood cells. Four cases failed to improve under this method of therapy.

3. The data obtained from a careful study of the use of red blood cell paste in 24 patients with indolent ulcers, old infected burns and extensive granulating wounds was tabulated.

4. Fifteen indolent ulcers which had been found resistant to other methods of therapy were treated with the local application of red blood cell paste. Nine of ten varicose ulcers were healed and only one failed to improve. Two cases with ischemic ulcers healed. One case (complete paraplegia) with an extensive decubitus ulcer was healed completely; another showed definite and progressive improvement, but a third with multiple extensive decubitus ulcers of long duration failed to respond.

5. Other lesions, such as infected burns and extensive granulating wounds, favorably responded to this method of therapy.

6. These results show that a by-product of plasma production may be utilized as an effective therapeutic agent in the treatment of open wounds.

Clinical Notes, Suggestions and New Instruments

BILATERAL SPONTANEOUS PNEUMOTHORAX

MAJOR ALBERT C. KING AND CAPTAIN MURRAY BENSON
MEDICAL CORPS, ARMY OF THE UNITED STATES

Chief and Assistant Chief Respectively of the X-Ray Service

In a series of over 5,000 patients we have had 4 instances of spontaneous pneumothorax. One of these proved to be of tuberculous origin. All 4 occurred on the right side. Three of the patients recovered completely. The case we are reporting ended fatally. The condition of pneumothorax simplex was first described by MacDowel in 1856. In some of the cases described a rupture of a valve vesicle on the lung was thought to be the cause; in the majority of the cases no cause was found. In about 25 per cent of cases recurrence in the same lung field was reported. An uncommon form, called the alternating type, was found in a small percentage of cases. In this type one pneumothorax healed fully, and some time later the other lung developed a pneumothorax. The rarest type was the bilateral spontaneous pneumothorax, in which one side ruptured before the original rupture had time to heal. It was because of this rarity that this case was presented. Being far removed from sources of statistics, we do not know how many cases of this type have been reported. We hope this case will add to the record.

REPORT OF CASE

On Aug. 19, 1943, a white soldier aged 27 was admitted to the hospital because of pain in the left side of the chest. There was nothing remarkable in his family history. His mother died of carcinoma of the uterus. His father was killed in the mines. One brother has "miners' asthma." One younger sister died of heart trouble. Five brothers and two sisters are living and well. As a child he had measles, mumps and chickenpox. As a youngster he was struck by an automobile and remained in coma for twenty-four hours. In 1928 he had his tonsils removed. In civilian life he was employed by an advertising firm. In the Army he was trained as an airplane

4. Seldon, T. H., and Young, H. H.: Use of Dried Red Blood Cells in Wound Healing. *Proc. Staff Meet., Mayo Clin.* 18:355-359 (Oct. 29) 1943.

Major Henry C. Harris, Chief of the Medical Service, and Captain Marvin N. Solomon, Chief of the Laboratory Service, helped in this case.

mechanic. He has been in the Army twenty months and has had no previous hospital admission. On August 7 he developed a severe type of diarrhea, nonspecific in nature. This lasted eight days, and he recovered completely under symptomatic treatment. He was well until the morning of August 18, when he developed a pain in the center of his back, following

Fig. 1.—Left pneumothorax, Aug. 19, 1943.

Fig. 2.—Reexpansion of left pneumothorax, Aug. 23.

the lifting and turning around of a fighter plane. He continued to work, however, and remained on duty without much difficulty. The next morning, August 19, while resting in bed, he was suddenly taken with an agonizing pain in the left side of the chest and especially in his left shoulder region. As he described it "it seemed like the strangest sensation; my chest filled up with gas and my left chest seemed to tighten upon me." It is interesting to note that the first medical officer to see him a short while later found him improved but noted a rigid abdomen and sent him into the hospital with a tentative diagnosis of perforated duodenal ulcer.

The patient was well developed and nourished. He was not in acute distress. His color was good, though there was a tinge of cyanosis to his lips. His pulse rate was 92, respiratory rate 26, temperature 97.8 F. and blood pressure 110/80. A routine urine examination and complete blood count were non-contributory. The left side of the chest bulged laterally. There were no breath sounds in this region. Percussion revealed intensified hyperresonance in the entire left chest. His heart was slightly displaced to the right. He was given codeine and later pentobarbital sodium. In a short time, he felt better and had a restful night. He was carefully watched for a possible tension pneumothorax.

On August 23 breath sounds were heard in the upper part of the left chest. He felt well. There was no dyspnea nor cyanosis. He was doing very well, when on August 29, ten days after his admission to the hospital, at 4:50 a. m., he suddenly became extremely dyspneic and resembled a patient in a severe asthmatic attack. It is interesting to note that thirty minutes prior to this the nurse found him sleeping peacefully. Examination now revealed that his breathing was entirely abdominal. There was no expansion of either side of the chest. A few breath sounds were heard in the left chest but none in the right. He became very cyanotic and complained of agonizing pain in his right chest and right shoulder. His respirations rose to 60 per minute; they were labored and gasping in character. Air hunger became manifest. His pulse rose to 160. It was regular, though poor in quality. Hyperresonance was present in both chests, more so on the right. His condition appeared critical.

The patient was placed in an oxygen tent. A needle was then introduced into the fifth right interspace in the outer

axillary line. Air rushed out under considerably increased pressure. Immediately the patient's air hunger was relieved. His breathing became less gasping and struggling in character. His color improved. Subaqueous drainage was instituted. At 5:50 his respirations were down to 34. His pulse rate dropped to 120. A slight cyanosis remained. He was very cooperative and had no pain in his chest. At 7 p. m. of the same day his pulse rate fell to 90. His respirations remained at 34, and he was comfortable and had no complaints. At 11:50 p. m. he suddenly became restless. Though his respiratory rate remained at 35, he suddenly developed intense air hunger. He appeared struggling for air while in the oxygen tent. His pulse was 76, and cyanosis was moderate. On August 30 at 9 a. m. his respirations suddenly dropped to 18, his pulse rose to 140 and cyanosis became deep. He became mentally depressed and did not respond to any painful stimuli. His pupils were pin point. The total amount of morphine administered in the past twenty-four hours was $1\frac{1}{2}$ grains (0.1 Gm.). At 9:50 a. m. his respirations were deep and of Cheyne-Stokes character. His pupils became dilated. Tracheal rales became audible. Cyanosis deepened and became generalized. He was perspiring freely. He died at 10:25 a. m.

An autopsy was performed several hours after death. Both lungs were found collapsed within their respective cavities. That of the left was slightly more expanded than that of the right. There was less than 10 cc. of free fluid in the left chest cavity. The heart was slightly displaced to the right. The right auricle was much distended. The right ventricle was also greatly distended. On the medial aspect of the left upper lobe, about 5 cm. below the apex, was a small area that was slightly raised from the surrounding pulmonary tissue, about 8 mm. in diameter, the center of which had a small tissue defect.

There was no evidence of a tear in the serosa of the right lung. There was no evidence, either by gross or by microscopic examination, of tuberculosis. The rest of the autopsy was non-contributory.

The anatomic diagnosis was atelectasis, pulmonary, bilateral, caused by pneumothorax, pulmonary, bilateral, spontaneous.

Fig. 3.—Left and right pneumothorax, August 27, 7 a. m.

Fig. 4.—Left and right pneumothorax, August 27, 11 a. m.

We were fortunate in taking x-ray films of each pneumothorax. Figure 1 reveals the first left pneumothorax and was taken on the day of admission. Figure 2 reveals a partial expansion of the left pneumothorax and was taken on August 23. Figure 3 reveals a right pneumothorax in addition to the previous left pneumothorax and was taken on August 27 at 7 a. m. Figure 4 reveals similar findings as in figure 3 and was taken the same day but four hours later.

A NEW RAPID METHOD OF INTUBATION WITH
THE MILLER-ABBOTT TUBE

FRANKLIN I. HARRIS, M.D., SAN FRANCISCO

One of the major advances in the treatment of small bowel obstruction has been the development of the technic of intestinal intubation with the Miller-Abbott tube. Numerous reports show a considerable decrease in the deaths from intestinal obstruction when this method has been used. This reduced mortality depends, however, on a successful intubation and the maintenance of continuous suction of the obstructed bowel.

Intubation of the Miller-Abbott tube into the small bowel has been at times extremely difficult and occasionally impossible. Many patients are denied the life saving advantages of this treatment because of failure to master the technic of intubation. The principal obstacle to successful intubation is in the passage of the tip and its attached rubber balloon through the pylorus and into the duodenum. The tube has frequently a tendency to coil and even twist itself into a figure of eight knot in the stomach. Even if no coiling takes place, the tip may float along the lesser curvature for many hours and engage itself in the antrum or the pyloric ring. In the desperately sick toxic patient this delay may be extremely serious. Occasionally the tube may enter the duodenum but descend no farther even after inflation of the balloon. The urgent need for a more certain and rapid method of facilitating passage of the tip through the pylorus and duodenum has been recognized by all surgeons using intubation. The standard methods are well known and have been adequately described by Blodgett¹ and other writers. These methods need no further elaboration and are familiar to all who use intestinal intubation. The use of a wire stylet to pass the tip rapidly through the pylorus has recently been advocated by W. Osler Abbott.² I have had no experience with this method, but it seems quite complicated and not

to secure certain passage of the tip of the Miller-Abbott tube into the small bowel. Although Wilkins³ in 1928 used metallic mercury as a weight in the bucket of his single lumen nasal tube, its use in the double lumen tube in the manner herein described is original. The idea of using metallic mercury within the rubber balloon attached to the tip of the Miller-Abbott tube was originally considered because of its great weight and its fluidity and flexibility as well as because metallic mercury, when accidentally swallowed, rapidly passes through the entire intestinal tract and is excreted without any poisonous effect. It was hoped that the introduction of metallic mercury

Fig. 3.—Eight hours later, continued descent of Miller-Abbott tube without air inflation. Small bowel obstruction practically completely relieved (case 2).

Fig. 4.—Position of Miller-Abbott tube twelve hours after introduction with mercury and air inflation of the bag (case 2).

into the rubber balloon might act to carry the tube rapidly into the small intestine.

An experience with 19 cases of small bowel obstruction during the past two years has justified this hope. With the use of this new technic there has been no failure in passing the tube into the obstructed bowel. The length of time necessary to pass the tube has been considerably shortened, and it has been also demonstrated that the weight of the mercury itself may carry the tube down the obstructed intestine without even inflating the rubber bag. This preliminary report is intended only to describe this new aid to intestinal intubation. At a later date a more comprehensive report will be presented covering this series of cases.

TECHNIC

If metallic mercury is to be used in the Miller-Abbott tube, the rubber bag should be carefully tested before introducing the tube into the stomach. This bag should be tested for air capacity and freshness of the rubber. The tube is then passed by the nasal route into the stomach in the usual manner. After the stomach has been emptied of its contents the patient is placed on his right side in the semi-Fowler position and from 4 to 8 cc. of liquid metallic mercury is injected into the rubber balloon through the smaller inner lumen of the double lumen tube. This injection is done by means of a 10 cc. luer syringe. The rubber bag, however, is not inflated with

air at this time. The optimum amount of mercury to be used has not as yet been exactly determined and does not appear to be of great importance. In this series the minimum amount has been 4 cc. and the maximum 8 cc. After the injection of the mercury the drainage lumen is connected to a continuous Wangenstein type of suction and the character of the drainage

Fig. 1.—Small bowel obstruction due to wound dehiscence (case 1).

Fig. 2.—Miller-Abbott tube filled with mercury passed into small bowel eight hours after surgery. Note that there is no air in the bag (case 1).

without danger of perforating the bowel or stomach. Abbott reports only two failures with this method in eighteen attempts.

My purpose in this preliminary report is to describe an experience with the use of liquid metallic mercury as an aid

3. Wilkins, J. A.: Mercury Weighted Stomach Tube, *J. A. M. A.* 91:295 (Aug. 11) 1928.

carefully noted. About every fifteen minutes 1 inch of the tubing is fed into the stomach. In some patients within one-half to one hour the tube will start moving down spontaneously. It is important that a loop of slack tubing be left alongside the nares so that this spontaneous descent may be observed. In some cases it will take from two to six hours before the tube starts to descend spontaneously. When the appearance of the drainage changes to characteristic yellowish green small bowel contents or the tube has spontaneously been drawn into the stomach over 12 to 18 inches, it is assumed that it is then in the upper small bowel. It is then advisable to take a flat x-ray film, which will more accurately show the position of the tube. The mercury in the bag is an excellent opaque substance to demonstrate the exact position of the head of the tube (fig. 1).

If there is definite proof of its passage beyond the pylorus by x-ray or by the presumptive signs described, the rubber bag may be inflated with 25 to 40 cc. of air and the standard technic of the Miller-Abbott tube procedure then used. However, in the last 6 cases inflation of the rubber bag was not done. It was found that the weight of the mercury in the bag was sufficient to carry the tube well down into the obstructed bowel. If subsequent experience substantiates this observation it will be unnecessary to inflate the rubber bag and will give rise to the possibility of using a single lumen tube weighted with mercury for purposes of intestinal intubation. I have under consideration the use of such a tube experimentally and clinically as soon as I am able under wartime conditions to obtain its manufacture.

The withdrawal of the Miller-Abbott tube when used with mercury in the rubber bag is no more difficult than with the regular technic. If air has been used to inflate the bag, the air must first be removed to collapse the bag preparatory to removal of the tube.

The use of mercury in the manner described seems to eliminate the one great technical obstacle to certain and rapid intubation. Objection might be raised to this method on the theory that there is possibility of rupture of the rubber bag, which would permit the escape of free metallic mercury into the intestinal tract. This accident has not yet occurred in my experience, but should it happen there is little danger of mercury poisoning. Metallic mercury is not supposed to be a poison. According to the United States Dispensatory (1907 edition) mercury is sometimes given in the metallic state in quantities of a pound or two in obstruction of the bowel and acts by its weight. In the uncombined state it is inert and insoluble in ordinary solvents and even in concentrated hydrochloric acid. Dr. A. Rossen, former surgical resident at Mount Zion Hospital, has fed metallic mercury to laboratory animals such as dogs and guinea pigs in the amount used in the Miller-Abbott tube, and the metal has rapidly been eliminated without any apparent toxic effects. Search of the available pharmacologic textbooks has failed to show any definite statement that metallic mercury is poisonous. If the rubber bag is carefully tested by inflation with air before its introduction, the danger of leakage or breakage is most remote.

SUMMARY AND CONCLUSIONS

Liquid metallic mercury in amounts of from 4 to 8 cc. has been injected into the rubber bag of the Miller-Abbott tube to facilitate a more rapid and certain intubation.

In a series of 19 consecutive cases of obstruction of the small bowel the Miller-Abbott tube has been quickly and successfully introduced with the aid of this new technic.

It appears that the weight of mercury itself may carry the tube into the small bowel without the necessity of air inflation of the rubber bag.

Clinical and experimental work is contemplated with a new type of single lumen, mercury weighted, intestinal tube.

450 Sutter Street.

A NEW NASAL CATHETER HOLDER

ROLF C. NORRIS, M.D., AND H. FRANK McCARTHY, M.D.
Senior Surgeon and Associate Surgeon, Respectively,
Lawrence General Hospital
Lawrence, Mass.

It occurred to us that the ordinary methods of holding a nasal catheter in place might be improved on. With this in mind several pieces of apparatus were tried, including some that have previously been described, but we feel that the

Fig. 1.—Nasal catheter holder.

simplicity of this holder, its inexpensiveness and the effectiveness of its use, particularly in the comfort to the patient, warrant its description to the medical profession.

It is composed of a piece of elastic suspender for a head band with a buckle attached; a swivel, double adjustable unit through which the elastic is passed, and a piece of hollow

Fig. 2—Holder in use

metal tubing through which the nasal catheter is passed for satisfactory holding. The tubing may be adjusted in two planes to fit any patient.

The accompanying illustrations show the apparatus itself and the view of a patient five days after an intestinal resection. The patient had worn this continuously since his operation and had no complaints. This holder has also been used on other patients and there have been no apparent discomforts or criticisms.

From the surgical service of the Lawrence General Hospital.

UNTOWARD EFFECTS OF ENDOCRINE THERAPY

SINCE THE NUMBER OF HORMONE PREPARATIONS HAS INCREASED DECIDEDLY IN THE PAST DECADE, MANY PHYSICIANS FIND IT DIFFICULT TO KEEP ABREAST OF THE RAPID ADVANCES IN THERAPY. THE INCREASED POTENCY OF SEVERAL ENDOCRINE PREPARATIONS IMPLIES AN INCREASED DANGER FROM CARELESS USE. MUCH OF THE EASILY AVAILABLE INFORMATION ABOUT THE NEWER PRODUCTS IS DRAWN FROM PACKAGE INSERTS OR PROMOTIONAL LITERATURE WHICH ARE NOT ALWAYS ENTIRELY UNBIASED. IT SEEMS WORTH WHILE ASSEMBLING A DISCUSSION ABOUT THE TOXIC EFFECTS WHICH MAY RESULT FROM MISTAKEN OR INDISCRIMINATE USE OF HORMONE. THIS WILL HELP PHYSICIANS TO RECOGNIZE LIMITATIONS AS WELL AS POSSIBILITIES ATTENDANT ON THE PRESCRIPTION OF POTENT ENDOCRINE PRODUCTS. DR. RUTH H. ST. JOHN, OF OHIO STATE UNIVERSITY COLLEGE OF MEDICINE HAS BEEN OF ASSISTANCE IN THE PREPARATION OF THIS REPORT.

AUSTIN E. SMITH, M.D., Secretary

THYROID MEDICATION

The complications arising from the clinical use of thyroid may be divided broadly into two groups: first, toxic symptoms resulting from uncontrolled and unphysiologic use of thyroid; second, toxic effects from overdosage in cases demonstrating pathologic complexities.

Desiccated thyroid has come to be regarded as a potent and relatively safe therapeutic adjunct in a variety of conditions other than true hypothyroidism. It has three desirable but potentially dangerous attributes: it acts as a stimulant, it is orally effective and it can be obtained at low cost. These properties have led to a widespread empirical use by the doctor and to self medication by the patient.

Production of hyperthyroidism, with the accompanying symptoms of accelerated heart action, profuse sweating, diarrhea and nervousness, is the condition to be most feared in uncontrolled thyroid medication. All too frequently patients who have been placed on thyroid therapy will fail to report for periodic examinations. Responsibility for such failure must rest to a great extent with the physician. It is important to stress the need for follow-up examinations and in many cases to regulate the dosage, depending on the ability of the patient to follow instructions. Also the physician must be constantly aware that in thyroid he is dealing with a powerful metabolic regulator, and critical judgment must be employed when the temptation arises to prescribe it in the absence of clinical signs of hypothyroidism. This is particularly true in cases of obesity in which no thyroid deficiency can be demonstrated. If weight reduction does occur concomitant with its use, it is generally felt to be due to the production of a pathologic state of hyperthyroidism.¹ Critical thought must also be given to the empirical use of thyroid for prepuberal and adolescent girls. Whereas apparent beneficial stimulation is frequently obtained, it would appear that the unintentional production of a hyperthyroid state might have serious effects on the organism as a whole and specific damage might occur to the delicate balance of the thyrogonadal relationships which are present at this time.² It is also possible that normal thyroid function may be reduced by the long continued use of thyroid in high dosage levels.³

The second group of toxic complications embraces the less frequent but very serious effects of high thyroid dosage in certain disease entities. Recently attention has been directed to a condition termed "pituitary myxedema."⁴ These patients present, in addition to the common signs of thyroid deficiency, additional signs of hypopituitarism and low adrenal function. High thyroid dosage will precipitate in such cases the dangerous symptoms of the acute crisis typical of adrenal insufficiency. Obviously, thyroid therapy used in Addison's disease would subject the patient to the identical danger of producing such a crisis.

In true myxedema the heart picture is one of potential myocardial insufficiency. Care must be used in establishing the individual tolerance of the patient to adequate thyroid dosage in order to avoid undue strain on the weakened heart.

The presence of coronary heart disease is also a contraindication to high thyroid dosage. It is extremely important in all adult patients for whom thyroid therapy is contemplated to obtain a careful history and physical examination in the search for the possible existence of coronary disease.⁵

It is often noted that in the presence of severe thyroid deficiency the initial doses of thyroid are at times poorly tolerated. When this occurs the physician holds a definite responsibility to his patient, particularly in the hypothyroidism of childhood. Thyroid therapy should not be abandoned if the need for it has been accurately determined.⁶ Lower dosage levels should be tried, and it is possible that there may be a variation in the clinical response to different commercial thyroid products.

It is extremely important for the physician to realize the variation which exists in the potency of thyroid extracts.⁶ In order to maintain carefully controlled medication it would seem wise for the physician to make use of preparations which meet the requirements of the U. S. Pharmacopeia for standard thyroid.

ADRENAL CORTEX EXTRACTS AND DESOXYCORTICOSTERONE

The availability of potent adrenal extracts and of synthetic desoxycorticosterone has meant the maintenance of life for many patients with Addison's disease. So far there has been no evidence of toxic effect incident to the use of natural adrenal cortex extracts in treatment of true adrenal insufficiency.⁷ Possibly the only danger in the use of adrenal cortex extract is that of inadequate dosage. Some of the commercial preparations have been of low potency, and it is important for the physician to assure himself of the potency of any product he prescribes until a definite standard of potency has been adopted.

The use of desoxycorticosterone acetate, which has the advantage of higher potency and lower cost, presents a number of hazards. Desoxycorticosterone does not control carbohydrate metabolism. Additional measures must be employed to treat the hypoglycemic trends which characterize Addison's disease.⁸ In the use of this synthetic drug there are decided dangers in over-

medication and in uncontrolled medication. Such complications of therapy include edema, hypertension, cardiac insufficiency, muscular weakness, joint and muscular pains and hypoglycemia. These toxic reactions are due in general to the increased load on the cardiovascular system resulting from the increase in blood volume and blood pressure and to the pronounced retention of sodium chloride and the lowering of serum potassium. Careful regulation of sodium, potassium and water intake is important in the therapeutic regimen.⁹ It is also important for the clinician to familiarize himself with approved dosage levels in the use both of the synthetic and of the natural hormone, since it is not always possible, particularly in an emergency, to rely on commercial literature for directions.

Experimental work has been conducted in the use of adrenal cortex preparations in conditions other than Addison's disease. Surgical and traumatic shock, asthenia, hypotension and fatigue are some of the clinical conditions for which the use of the extracts has been urged. In general, the results have been disappointing and have failed to substantiate the commercial claims. The general practitioner who wishes to attempt such empirical therapy should be aware of the possibility of toxic complications when the synthetic hormone is used.

ESTROGENIC SUBSTANCES

Estrogen therapy has become increasingly popular in the last few years, and the introduction of the inexpensive and orally effective synthetic stilbestrol derivatives has contributed greatly to the hazards incident to uncritical use. Fortunately the toxic complications of nausea, headache and general malaise, which occasionally occur in the course of diethylstilbestrol therapy, are transitory and may usually be controlled by reducing the dosage level.¹⁰ There is apparently no evidence to substantiate the fear that serious liver, kidney or bone marrow damage may develop,¹¹ but careful investigators realize the clinical uncertainty which exists regarding drugs that are capable of producing toxic effects.¹²

The abnormal degree of endometrial hyperplasia which may result from excessive or prolonged administration of natural or synthetic estrogens should be a source of some apprehension. Two primary possibilities should be considered. First, a persistent effect may be produced leading to cystic endometrial glands,¹³ and, second, such hyperplasia might stimulate a latent neoplastic growth.¹⁴

It has been shown that some hormones exhibit a carcinogenic property in animals. This is particularly true of estrogens.¹⁵ A carcinogenic effect has not been demonstrated in human beings,¹⁶ but the proliferative action of estrogens on the endometrium must be regarded as a potential stimulator of preexisting neo-

plastic growth. With this in mind, prolonged administration of estrogenic materials should be guarded against, particularly with patients who present a hereditary background favoring neoplastic growth.¹⁷ Frequent pelvic examinations should be made in the course of estrogen therapy, particularly when estrogen withdrawal bleeding has been known to occur, in order to differentiate between such bleeding and that of early cancer.

There is a considerable degree of misunderstanding with regard to the choice between estrogens and gonadotropic materials in the correction of menstrual disorders. Estrogenic substances do not stimulate ovarian function. They may be used to stimulate uterine growth and development in hypoplastic conditions and may be relied on as replacement medication in primary ovarian failure and in natural or surgical atrophy or removal of the ovaries; but, when ovarian stimulation is sought, pituitary or equine gonadotropic materials must be employed.

There are many types of ovarian dysfunction in which estrogen therapy has been employed. In general it might be said that the rationale of such therapy in conditions other than those mentioned is the attempt at restoring what is regarded as a disturbed physiologic balance between estrogens and progesterone. When such therapy is used, a cyclic plan should be followed. Pathologic effects may result from the unphysiologic use of an estrogen in the last half of the menstrual cycle. There is evidence that normal corpus luteum function may be depressed with resultant short cycles and variable flows.¹⁸ When large doses of an estrogen are used in young women, ovulation may be inhibited. This procedure has been employed as a means of treating dysmenorrhea and would appear to be an undesirable practice during the child bearing age.¹⁹

PROGESTERONE

Progesterone therapy is being tried in a variety of gynecologic conditions, but as yet its uses are not clear.²⁰ It is a replacement for deficient corpus luteum hormone activities and does not have a direct stimulative effect on the ovaries. It is thought by some investigators to be of value in certain types of dysmenorrhea, in habitual abortion and in functional uterine bleeding.²¹ Other reports show disappointing results in these conditions, particularly with regard to the quieting effect of progesterone on uterine muscles.²²

Substitution therapy combining estrogens and progesterone in a cyclic plan of treatment has been effective in inducing normal menstrual cycles both in amenorrhea and in functional bleeding.²³ However, the expense of progesterone medication is prohibitive in many cases, and critical judgment should be employed before subjecting the patient to an experimental type of therapy.

The physician must also be warned against the use of unstandardized preparations. There are still corpus luteum extracts on the market which contain little if any of the active progesterone.²⁴

TESTOSTERONE

Use in the Female.—Testosterone propionate (injectable) and methyl testosterone (oral) have come into recent use in the female as a means of inhibiting abnormal uterine bleeding. Although the mode of action has not been definitely determined, it is thought that these compounds may act by suppression of pituitary gonadotropic activity, by inactivation of estrogens or by inhibition of the proliferative capacity of the endometrium.²³

There is a justifiable fear attendant on such therapy, since masculinizing symptoms have been known to appear. These symptoms, frequently referred to as "arrhenomimetic," include excessive hair growth, hoarseness, deepening of the voice, acne and enlargement of the clitoris.²⁴ The dosage level is of great importance. Such masculinizing effects have rarely occurred when the total dose has been kept under 300 mg. per month. Fortunately, if such symptoms do occur, they are usually transitory, seldom persisting more than a few weeks following cessation of therapy.²⁵ However, cases have been reported of voice changes persisting more than two years after discontinuing therapy.²⁵

It is generally agreed that androgen therapy should be carefully controlled to avoid such difficulties and that the use of the vaginal smear for estrogenic activity provides a reliable indicator of the suppressive action of the androgenic hormone. Vaginal smears will demonstrate the degree of estrogenic depression long before the clinical occurrence of arrhenomimetic symptoms.²⁶

Use in the Male.—In the male, androgen therapy has been regarded with certain misgivings when used in prepuberal and adolescent boys. Fears have been expressed regarding the possibility of producing precocious puberty,²⁷ premature closure of the epiphyses with the subsequent stunting of growth²⁸ and atrophy of the testicles.²⁹ Recent studies are more optimistic and tend to stress the stimulating effects on growth and genital development.³⁰ Since testosterone therapy is still in an experimental state, the patient under treatment must be carefully observed for untoward effects and the dose varied according to individual response.

In castrate and eunuchoid cases and in the male climacteric, testosterone provides a potent replacement therapy.²⁷ Oral medication with methyl testosterone has proved satisfactory and has facilitated such treatment, but both oral and parenteral therapy are expensive to the patient, since the treatments are often neces-

sarily prolonged. Only occasionally have the transient effects of headache or nausea appeared with the use of testosterone.

GONADOTROPINS

Gonadotropic material is available from three sources: (1) chorionic, obtained from the urine or placenta of pregnant women; (2) the combined pituitary hormones obtained from extracts of the anterior pituitary lobes of domesticated animals; (3) gonadotropic substances obtained from the serum of pregnant mares.

Chorionic Gonadotropins.—It is generally conceded that chorionic gonadotropins do not have the properties attributed to pituitary or equine gonadotropins. Chorionic material does not stimulate the ovary to follicle formation or to ovulation, nor can it be utilized in other instances when substitution therapy is required for anterior pituitary deficiency.³¹

In the female, chorionic gonadotropins are apparently of some value in sustaining corpus luteum function, but this factor has not as yet been proved to be of clinical value.³² The use of chorionic material in functional bleeding and in dysmenorrhea has no sound scientific basis,³³ and recent investigations tend in general to discourage its use in gynecologic practice.³⁴ Other benefits which commercial literature claims for the use of chorionic gonadotropins have not as yet been proved to be dependable. Obviously, its therapeutic value is still in the experimental stage.

In the male, chorionic gonadotropins have been shown to act as a potent stimulator of the interstitial tissue of the testicle which justifies their use in treatment of undescended testicles and genital underdevelopment. Frequent observation of the patient is to be urged in order to avoid excessive enlargement of the genitalia which may result from prolonged administration of the material.³⁵ It is thought by some investigators that antibody formation will occur in the course of long continued therapy, and perhaps this development may be avoided by discontinuation of the injections at regular intervals.³⁶

Pituitary and Equine Gonadotropins.—In spite of lack of certainty regarding the exact nature of the pituitary hormones and the subsequent difficulties encountered in standardizing commercial products there are a number of such preparations on the market, and many claims are made for their use.

There are a number of limitations in the use of gonadotropic material. In spite of continued attempts to reduce the protein content of the material, the patient may exhibit an allergy to these proteins, with symptoms varying from mild local reaction at the site of injection to severe anaphylactic shock. It is also possible that sensitivity may develop following a course of treatment, with serious results from subsequent injections.³⁷ Antibody formation is also to be considered; discontinuing injection at regular intervals during a course of treatment is thought to reduce this risk.³⁸ The chief handicap, however, in the clinical use of pituitary and equine gonadotropins is the low and

variable potency and the high cost of commercially available preparations. All these factors make it extremely important for the physician to give his patient the benefit of a careful and critical diagnostic appraisal before subjecting the patient to a long, expensive and possibly futile course of therapy.

In the female, endometrial biopsies and vaginal smears for determining estrogenic activity are extremely valuable diagnostic measures to be employed in evaluating the initial degree of ovarian activity and the possibility of obtaining response to gonadotropic therapy. When primary ovarian failure is shown to exist, no stimulative action may be expected to result from the use of gonadotropic therapy. If the ovarian dysfunction is thought to be the result of inadequate pituitary stimulation, pituitary or equine gonadotropins may be useful. It has been suggested that equine gonadotropins possibly have a more specific gonadal effect than anterior pituitary lobe preparations, since the latter must necessarily include other pituitary hormonal factors.³⁷ However, it is generally conceded that gonadotropic therapy is still unsatisfactory and will remain so until pure gonadotropic principles can be elaborated from the anterior pituitary lobe.³⁷

In the male, certain types of infantilism or delayed puberty may respond to pituitary or equine gonadotropic therapy with the result of increased growth and genital development.³⁸ In all conditions, in both male and female, symptomatic improvement after a reasonable trial of therapy must necessarily be a measure of successful therapy. If no beneficial changes occur, there is no value in continuing the therapy.³⁸

Recently an attempt has been made to determine the synergistic effect of combined chorionic and pituitary gonadotropin. There is one such mixed product on the market. The clinical effect in human beings is still under investigation.³⁹ Experimental work indicates a very high degree of stimulation in rat ovaries with use of the combined preparations. Although the manufacturers of the product warn against uncritical use of the material, it has nevertheless been used without proper concern for the possible deleterious effect on the ovaries.

PITUITARY GROWTH HORMONE

There are several pituitary products on the market which are claimed to contain a relatively high concentration of the "growth factor."⁴⁰ Since it is still impossible to isolate or identify the separate principles of the pituitary hormone, the potency of such products must remain questionable. An attempt at standardization has been made, using rat growth units, but such standardizations are not uniform as between competing products. The complications involved in the use of growth hormones are the same as those described for any of the pituitary gonadotropic materials.

If the use of the growth promoting factor is to be considered, the physician owes it to his patient to explain the experimental nature of such therapy. The physician must also be aware of the complex relationships between growth and genital development and should insist on frequent observation of the patient in order to avoid untoward effects. In cases of uncomplicated dwarfism, when x-rays show the epiphyses of the

long bones to be open, growth has been stimulated in a number of reported cases, but unfortunately such response is not dependable.⁴¹

POSTERIOR PITUITARY PRODUCTS

The commercial products of the posterior lobe of the pituitary gland include the water soluble principles of the whole posterior lobe, the powdered posterior pituitary substance and the fractionated extracts described as oxytocic and pressor factors. The therapeutic effects of these products are related to cardiovascular, renal, gastrointestinal and obstetric action.

There have been many reports of hypersensitivity to these products.⁴² In general, the toxic effects are those of shock, with symptoms of pallor, rapid pulse, fall in blood pressure, air hunger, edema and coma. These symptoms may be alleviated by the use of epinephrine.

Certain specific dangers may be related to the cardiovascular effect, and care should be used in administering posterior pituitary products to patients who have pre-existing heart disease. The specific dangers of careless use of the oxytocic principle in obstetric cases are fairly well known. Rupture of the uterus, laceration of the cervix and cardiac death due to the sudden strain of physical exertion in labor are some of the reported effects of uncontrolled therapy.

The intestinal stimulation obtained by use of the pressor fraction is of clinical value in treatment of paralytic ileus and postoperative distention but may be a source of toxic irritation in the long continued use of posterior pituitary substance in treatment of such conditions as diabetes insipidus. Too large a dose will occasionally produce intestinal cramping and pain, and it is important to adjust the dosage level to a point where such effects will be obviated.⁴³

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary.

NEO-SYNEPHRINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 284).

The following additional dosage forms have been accepted:

FREDERICK STEARNS & CO., DETROIT

Solution Neo-Synephrine Hydrochloride, ⅓ per Cent: 15 cc. neo-synephrine hydrochloride ⅓ per cent, sodium chloride 0.1 per cent, boric acid 2.2 per cent with chlorobutanol 0.4 per cent and sodium bisulfite 0.5 per cent as preservatives in an aqueous solution.

Solution Neo-Synephrine Hydrochloride, 2½ per Cent: 15 cc. neo-synephrine hydrochloride 2½ per cent, ascorbic acid 1.0 per cent as a stabilizer, chlorobutanol 0.4 per cent and sodium bisulfite 0.1 per cent as preservatives in an aqueous solution.

Solution Neo-Synephrine Hydrochloride, 10 per Cent: 4 cc. neo-synephrine hydrochloride 10 per cent, ascorbic acid 1.0 per cent as a stabilizer, chlorobutanol 0.4 per cent and sodium bisulfite 0.1 per cent as preservatives in an aqueous solution.

RIBOFLAVIN (See New and Nonofficial Remedies, 1944, p. 613).

The following dosage forms have been accepted:

WILLIAM R. WARNER & CO., INC., NEW YORK

Tablets Riboflavin: 1 mg.

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Tablets Riboflavin: 1 mg. and 5 mg.

DEFERMENT OF PREMEDICAL STUDENTS

Elsewhere in this issue (page 794) are published a letter from Congressman A. L. Miller of Nebraska to the President regarding current Selective Service regulations pertaining to premedical and medical students, and the President's reply. Granted that the premedical students involved will not become available as physicians until 1948, starting now and continuing until the war is over, students will commence premedical studies in utterly inadequate numbers. These lost premedical months or years cannot be regained after the war is over.

The President's suggestion that women and physically disqualified men can supply the need does not take into account the fact that qualified students in this category are not available in sufficient numbers now unless educational standards are drastically reduced. Furthermore, the study and practice of medicine are arduous, requiring vigorous health. These are not occupations for the physically unfit. The physically unfit cannot be expected to give an equal return in years of service to that given by those who are physically competent.

The same considerations must apply to discharged veterans. Many of these are physically unfit and emotionally unstable. This group will also include men who have previously been rejected for admission to medical schools because of failure to meet admission standards.

Certainly every favorable consideration should be given to medical school applications from veterans, to whom we are all immeasurably and forever indebted. But it would serve neither the veterans nor the public to admit to medical schools men who do not possess the required physical, emotional, mental and other qualifications.

PATHOGENESIS OF MYASTHENIA GRAVIS

In 1930 Harriet Edgeworth reported relief of asthenia, dysphagia, diplopia and disturbance of speech when she took ephedrine by mouth. Walker in 1934 administered physostigmine salicylate to a patient with myasthenia gravis because it was thought that the muscles in myasthenia behave like muscles poisoned by curare, so that physostigmine, an antagonist to curare, might counteract the unknown substance which seemed to be exerting a curare-like effect on the motor nerve endings. Subsequently a synthetic analogue known as neostigmine replaced physostigmine as the remedy of choice, owing to its less toxic side effects. The remarkable response to neostigmine given by hypodermic injections led to its use as a diagnostic measure by Viets and Schwab. These authors¹ gave neostigmine bromide orally to 44 patients with myasthenia gravis and supplemented it with ephedrine sulfate, potassium chloride and occasionally guanidine. Forty-three of their patients had a characteristic reaction to the combined therapy of neostigmine and ephedrine. Ephedrine increased the effect of the neostigmine in 41 of the 43 cases and failed in only 2. Aminoacetic acid did not prove to be useful. Guanidine increased the effect of neostigmine in a few cases and failed in many.

Studies by Dale and by Loewi demonstrated that acetylcholine is liberated on stimulation of the motor nerves supplying striated muscles. Physostigmine enhances and prolongs muscle contraction apparently by inhibiting the destructive action of cholinesterase on acetylcholine. The abnormal fatigability in myasthenia gravis has been thought to be due to curare-like poisoning of the motor nerve endings of the neuromuscular junctions in the affected muscles. Gammon and Scheie stressed the clinical observation that neostigmine, which produces fasciculations in the muscles of normal subjects and of patients in a variety of diseases involving the nervous and muscular systems, failed to elicit fasciculations in patients with myasthenia gravis. Harvey, Lilienthal and Talbot² showed that even high concentrations of neostigmine attained in a small localized area do not produce fascicular twitches in the myasthenic subject. The fundamental defect in myasthenia gravis lies in some disturbance of the neuromuscular transmitting mechanism. The repair of this defect by neostigmine, which is known to protect the acetylcholine release of motor nerve endings from hydrolysis by cholinesterase, supports the hypothesis that in this disease the normal metabolism of acetylcholine is deranged. In the normal subject neostigmine injected intra-arterially produces a profound local

1. Viets, Henry R., and Schwab, Robert S. The Diagnostic and Therapeutic Value of Myasthenia Gravis with Special Reference to the Use of Neostigmine. *J. A. M. A.* 112: 559 (Apr. 13) 1939.
2. Harvey, A. M.; Lilienthal, J. L., Jr., and Talbot, S. A. G. Effects of the Intra-Arterial Injection of Acetylcholine and Physostigmine in Normal Man. *Brit. J. Anaesth.* 60: 525 (Dec.) 1941.

paresis, which has been assumed to result from the accumulation of a paralyzing concentration of acetylcholine (Harvey, Lilienthal and Talbot). These authors conclude that the fundamental defect in myasthenia gravis is reduction in the quantity of the transmitting agent available or released. Acetylcholine when injected intra-arterially evokes in a myasthenic patient a powerful sustained contraction of the injected muscles. This is in partial contrast with the transitory weakness evoked in normal subjects. The analogy between myasthenia gravis and partial curarization suggests the hypothesis that a circulating inhibitory substance may be responsible for the primary neuromuscular defect. There is evidence to suggest that this hypothetical substance may arise from the thymus. This idea is supported by the experience of Blalock³ who has recorded the instant cure of severe myasthenia gravis by the removal of a cystic tumor from the thymic region. Several cases have been reported in which the removal of a thymic tumor or hyperplastic thymus has resulted in great improvement. Postmortem examination of patients with myasthenia gravis has shown that about 50 per cent have hyperplasia, tumor or persistence of the thymus.

Harvey and his associates⁴ reported great clinical improvement in 3 of 5 patients with severe myasthenia gravis following total extirpation of the thymus. The intra-arterial injection of neostigmine in contrast to the effect before thymectomy, now produced local fascicular twitching, repetitive response to a single stimulus, normal local paresis and a depression of neuromuscular transmission. These changes indicate an increase after thymectomy of transmitter substance available at the neuromuscular junction. Apparently in some patients the thymus assumed an important role in the pathogenesis of myasthenia gravis.

Wilson and Stoner⁵ found the serum cholinesterase activity in 14 patients with myasthenia gravis to be no greater than that of normal adults. Apparently the muscular weakness in myasthenia gravis is not due to an excessively rapid destruction of acetylcholine by cholinesterase. They were able to demonstrate by means of cinecamera and kymograph studies that exercise of a remote group of muscles produces an increase in the severity of the signs of the disease. They conclude that the most probable explanation of the phenomena of myasthenia gravis is the presence of some substance in the blood which produces a block in neuromuscular transmission and inhibits the normal action of acetylcholine on voluntary muscle. The thymus may play an integral part in the secretion or

control of this substance. The action of neostigmine on the myasthenic patient may be to produce some antagonistic effect on the inhibiting substance and thereby restore the normal threshold of the effector to acetylcholine.

METABOLIC DESTRUCTION OF MOTOR END PLATES

During postmortem rigidity a rapid disappearance of motor end plates occurs in human skeletal muscle, associated with a considerable local increase in hydrogen ion concentration. This increase is due mainly to a local accumulation of lactic acid, which usually reaches a concentration of from 0.05 to 0.3 per cent¹ in rigor mortis. The possible causal relationship between locally increased acidity and end plate degeneration was tested by Carey² of the Department of Anatomy, Marquette University, who studied the morphologic effects of intramuscular injections of lactic acid in white rats.

Under pentobarbital sodium anesthesia the right sternomastoid muscle was removed as a control and run through the gold technique³ and other histologic methods. Following this removal 0.1 cc of 0.05 to 0.3 per cent lactic acid in isotonic solution of sodium chloride was injected into the opposite sternomastoid muscle. The injected muscle was removed for microscopic study from thirty seconds to twenty-five minutes later. Comparison of the two exercised muscles revealed that there was a retraction of many of the end plates within thirty seconds after the acid injection, with a considerably increased staining reaction for gold, accompanied by a considerable dilatation of the epilemmal axons. This was soon followed by an abnormal expansion and decreased staining reaction of the end plates, with beginning fragmentation of the hypolemmal axons. By the end of twenty-five minutes many or, at times, practically all of the end plates and epilemmal axons had disappeared, the rate depending on the lactic acid concentration. In many muscle fibers there were clear oval spaces of liquefaction at the previous sites of the end plates. Electrical stimulation of the spinal accessory nerve showed that within thirty seconds the muscle was completely paralyzed by 0.05 per cent lactic acid.

The results of this study confirm the previous belief that acid metabolites which accumulate during rigor mortis are responsible for the local destruction of motor end plates. Carey is of the opinion that as a result of excessive or prolonged muscular activity a similar metabolic destruction of end plates may take place during life. This hypothesis offers a plausible explanation for the rapid destruction of motor end plates in experimental polyomyelitis in monkeys⁴ and suggests

new therapeutic methods. As early as 1851 it was shown by Brown-Séquard² that intravascular injection of alkaline solutions removes rigor in animals and reestablishes muscle irritability.

Current Comment

THE G. I. BILL OF RIGHTS

The broad objective of the Servicemen's Readjustment Act of 1944 is the integration of veterans of the present war into civilian life in the most prompt and adequate manner. Elsewhere in this issue (page 796) is an analysis of the new act, prepared by the Bureau of Legal Medicine and Legislation. Certain provisions of the act are of special interest to physicians in service, especially to the younger physicians. These younger physicians will return to civilian life faced with the necessity of establishing for the first time a civilian practice or of reestablishing a practice pursued only a short time before entry into service. Refresher courses will be made available under the title dealing with education, extending over a period of one year, with maintenance allowances. Machinery is set up whereby the Veterans' Administration will guarantee loans made to veterans for specified purposes, including the purchase of supplies and equipment to be used in a gainful occupation. A third title, in providing for adjustment allowances for unemployed veterans generally, will make available a similar benefit for veterans self employed for profit in an independent business or profession whose income during the preceding calendar month from that business or profession was less than \$100. The program authorized by this act will be a costly one to the nation but, as expressed by the Senate Committee on Finance, "The men and women who compose our armed forces and who will compose our armed forces before the end of the war not only now hold the destiny of this republic firmly in their hands, they will so hold it for a generation to come. To the extent to which these men and women can be speedily reintegrated into the civilian population, the consummation of all of our hopes and prayers for national security and advancement depend."

THERAPY OF SHOCK

The restoration of blood volume by administration of whole blood or blood substitutes has revolutionized the treatment of shock. As a result, many have overlooked that the reduced blood volume and the circulatory disturbances are easily followed by metabolic disorders which may be as important as the circulatory collapse itself. Govier and Greer¹ showed that the correction of the defective breakdown of glucose in the periphery by administration of thiamine prolongs significantly the survival time of dogs subjected to hemorrhagic shock and that a high thiamine intake increases the resistance of the animals against shock.

More recently Soskin and his group² have emphasized the importance in the treatment of shock of replenishing the cells with easily oxidizable substrates and of controlling acidosis. Irreversible hemorrhagic shock was produced by slow blood withdrawal in which 75 per cent of the dogs died in spite of being reinjected with all the blood that had been withdrawn. The correction of acidosis by addition of sodium bicarbonate to the whole blood reinjected reduced the death rate to 50 per cent. Combinations of the sodium ion and any easily oxidizable substrate such as glucose, lactate or succinate to the whole blood reinjected reduced the mortality rate of so-called irreversible shock to figures as low as 25 per cent. These studies demonstrate that the circulatory collapse is only a partial feature in the complex mechanism of shock. Hence its correction does not constitute more than a partial therapy of shock and one which is ineffective in the irreversible stage. To prevent the development of irreversible shock or to treat advanced shock adequately, consideration must be given to the secondary tissue damage as well as to the primary circulatory condition.

DISRUPTION OF HOMES BY DEATH OF PARENT

In excess of 500,000 families in this country are broken each year as a result of the death of husband or wife. According to the Statistical Bulletin of the Metropolitan Life Insurance Company,¹ more than 200,000 of the widows and widowers thus created have left in their care a total of almost a half million dependent children under the age of 18. In 1940, for example, approximately 360,000 wives became widowed by the death of their husbands. About one fourth of these women were under 45 years of age and another fourth fell in the age range from 45 to 54. Almost two fifths of these new widows of 1940 had children under 18 left in their charge; to practically half of the widows who were under 45 years of age there was left the task of caring for more than 150,000 children. In innumerable cases the widows with young dependent children were faced with serious hardships, principally of economic nature. Many undoubtedly had to seek employment and at the same time keep up a home for their children. Some solved their economic problem by remarriage, but the possibilities of this are reduced by the presence of dependent children. The problem of adjustment following the death of the marital partner is not so difficult for men as for women; the widower usually suffers no loss of income to provide for himself and his motherless children. Furthermore, the widower with dependent children is usually strongly inclined toward remarriage, and the obstacles to this are generally not as formidable as those facing the widow with young children. The disruption of homes containing young children by death of either parent represents not only a difficult problem but one which can never be entirely solved.

MEDICINE AND THE WAR

ARMY

THE MAYO GENERAL HOSPITAL

The Mayo General Hospital at Galesburg, Ill., was formally dedicated July 10, at which time the following program was presented

Band Concert	Camp Ellis Band
God Bless America	Camp Ellis Band
Accompanied by Post Choir and Audience	
Invocation	Catholic Chaplain Galesburg
Presentation of Building	Colonel Montgomery
Acceptance	Colonel Kraft
Brothers Mayo Army Experience	
Brig Gen Fred W Rankin Chief Consulting Surgeon U S Army	
War Department Policy in Care of Sick and Wounded	
Major Gen H S Aurand Commanding 6th Service Command	
History of Mayo Brothers	
Dr Donald C Balfour, Mayo Clinic Rochester Minn	
Benediction	Post Chaplain
National Anthem	Camp Ellis Band
Post Choir and Audience	

The hospital was named in honor of Drs William and Charles Mayo and is a tribute to their contribution to the medical service in the first world war. It is constructed on a 155 acre site at the north limits of Galesburg, and has seventy-seven buildings of red brick, all except eight of them of one story. A forty-five room administration building and nurses' and officers' quarters are two stories high. It has approximately 1,650 beds. The hospital has its own post office, telephone and telegraph office, post exchange store and lunchroom, laundry, gymnasium, recreation halls and medical and quarter-master warehouses. The hospital was officially opened February 1 and is now treating American soldiers brought back from war zones and those injured in training throughout the country.

The medical officers at present on duty are

Col Henry L Kraft commanding	Capt Francis C Lane
Col Emory B Neff	Capt Albert F J Johannann
Lieut Col Ford K Hick	Capt John C Mason
Lieut Col Jasper K Knott	Capt Stuart W Russell
Lieut Col Philip Lewin	Capt George F Sanders
Major Howard W Berg	Capt Charles M Schroeder
Major Casper M Epstein	Capt Albert O Singleton
Major Ralph H Fouser	Capt Max E Webber
Major Edward A Gill	Capt Norman T Wellford
Major Richard L Kinzer	Capt Harold I Weibel
Major Emanuel Krinsky	1st Lieut John A Vita
Major Paul K McConnell	1st Lieut Daniel H Byrenbaum
Major Edwin O Niver	1st Lieut Fustace G Hester
Major Martin Patmos	1st Lieut Robert E Lantz
Major Tim L Rippey	1st Lieut A G Richard Perlmi
Capt John J Andrina	1st Lieut Fric H Russow
Capt Howard G Billman	1st Lieut Archer I Sokol
Capt Emanuel G Bloom	1st Lieut Joseph J Speranza
Capt Harold W Christy	1st Lieut Robert G Swanson
Capt Willard Jeffrey	1st Lieut Harry Taylor
Capt John H Johnston	1st Lieut John B Westfall
Capt Willard Z Kernman	

MEDICAL CARE OF AMERICAN WOUNDED IN FRANCE

Major Gen A W Kenner, U S Army, chief medical officer, Supreme Headquarters, Allied Expeditionary Force, recently reported on the high standard and the great effectiveness of the medical care given to American soldiers wounded in France after visits to general hospitals in England, where they had arrived a few days after becoming casualties. Among 561 wounded, comprising two groups visited, not a single death had occurred. Most of them were wounded on D Day. General Kenner's visit was made on June 17, eleven days after D Day, as part of an inspection tour of general hospitals which had received evacuated casualties. Of the 561 men, 311 had gone to one hospital, 250 to another. Of the 311 patients received at the general hospital in England on the fourth day after D Day about half were ambulatory, and many already had been released from the hospital. Only two of the cases were in serious condition on arrival. Sulfonamide or penicillin treatment has been continued in all cases indicated.

The 250 battle casualties at the other hospital had arrived seven days after D Day. None were in shock, and all were reported as making satisfactory progress. None were psycho-neurotic.

From reports of medical personnel at these installations and from personal talks with many patients, General Kenner stated that almost without exception the morale of the wounded was exceedingly high. Great admiration was expressed for the medical service given on the beaches, LST, hospital carriers and ambulance trains.

THE GARDINER GENERAL HOSPITAL

The Gardner General Hospital in Chicago, the first army hospital to be named after a nurse, was formally dedicated July 9. A feature of the program was the presentation of a portrait of Lieut Ruth M Gardiner, after whom the hospital was named. Lieutenant Gardiner was killed in Alaska in July 1943 in an airplane crash while evacuating wounded soldiers.

The hospital was opened in December 1942 and has a bed capacity of 1,250. It is being used as a military hospital for the Army Air Force's Technical Training Command. Col John R Hall is commanding officer. Col Florence A Blanchfield, superintendent of the Army Nurse Corps and Brig Gen Fred W Rankin were present at the dedication.

Lieutenant Gardiner graduated with the second class of flight nurses from the School of Air Evacuation, Bowman Field Ky., on Feb 18, 1943 and left there for evacuation duty with the Eleventh Air Force in Alaska on April 22. She was the first army flight nurse to be killed in World War II.

U. S HOSPITAL DEDICATED

The new 600 bed Staten Island Arca Hospital overlooking Raritan Bay at New Dorp S I., which was recently dedicated, will be used to receive American soldiers wounded in the invasion of Europe, according to a recent announcement made by Major Gen A T Terry, commanding general of the Second Service Command. The hospital will primarily serve soldiers and Wacs stationed in the Staten Island area and members of their families. The hospital comprises forty-seven buildings, including eleven connected one story wards, a post exchange, three operating rooms and six wards in the main building.

ARMY AWARDS AND COMMENDATIONS

Brig Gen Malcolm C. Grow

The War Department recently announced the award of the Distinguished Service Medal to Brig Gen Malcolm C Grow. The following citation accompanied the award: "As surgeon for the Eighth Air Force from May 1942 to January 1944 he was assigned to duty, and without benefit of precedent he conceived, promptly initiated and aggressively carried out a new medical plan for the conservation of fighting strength of combat crews. Through extensive study and research of conditions affecting the health and efficiency of aircrews at high altitudes, he developed and placed in operation a device to protect gunners from wind blast, electrically heated clothing, gloves, boots, hand warmers and casualty bags for the wounded, wind and fire resistant face and neck protectors, and a special combat ration for use on long bombing missions. These innovations resulted in a pronounced decrease of frostbite cases and greatly increased the combat efficiency of the flight crews. To reduce loss of manpower from psychiatric failures in combat, his recommendations for a system of passes and leaves for combat crews was instituted. Rest homes for their exclusive use established and special training given all medical officers.

in the tactical units. As a result, every casualty of this type was returned to duty." Dr. Grow graduated from Jefferson Medical College of Philadelphia in 1909 and entered the service Sept. 6, 1937.

Colonel Franklin T. Hallam

The Legion of Merit award was recently presented to Col. Franklin T. Hallam "for exceptionally meritorious conduct in the performance of outstanding services as surgeon of a corps in the Solomon Islands from Feb. 28, 1943 to March 31, 1944. At Guadalcanal, where he contributed much to decrease substantially the malaria rate, Colonel Hallam was responsible in a considerable measure for the organization and coordination of joint Army and Navy medical services. Later he was of invaluable assistance to the corps commander in planning and executing the initial evacuation program in connection with combat operations at New Georgia. Through his efforts in this campaign, rest camps were established and so expertly operated

that hundreds of patients suffering exhaustion and nervous disorders were rehabilitated and returned to combat units in a minimum of time. Colonel Hallam's services again were distinguished at Bougainville, where he was largely responsible for the efficiency of medical installations and for effective malaria control." Dr. Hallam graduated from Indiana University School of Medicine, Bloomington, in 1925. He was commissioned a first lieutenant in the Indiana National Guard July 27, 1933 and was called to active duty Jan. 17, 1941.

Lieutenant Colonel Stephen L. Gumpert

The Legion of Merit was awarded by the War Department recently to Lieut. Col. Stephen L. Gumpert (then captain), Medical Corps, U. S. Army, "for exceptionally meritorious conduct in the performance of outstanding services during the period Jan. 25, 1942 to Jan. 28, 1943." Dr. Gumpert graduated from Cornell University Medical College, New York, in 1938 and entered the service July 12, 1941.

DEFERMENT OF PREMEDICAL AND MEDICAL STUDENTS

Following are the complete texts of the correspondence between the Honorable A. L. Miller, Member of Congress from the Fourth District, Nebraska, and President Franklin Delano Roosevelt:

My dear President:

I hesitate to bring before your busy office a problem which should be solved by the Director of Selective Service, General Lewis B. Hershey. I refer to General Hershey's order of April 11 which in effect will induct practically all premedical students into the Army by July 1.

I have had several conversations with General Hershey and his staff and it does not seem likely that they are willing to accept the responsibility and order a temporary deferment of men of military age who are now in our colleges as premedical students.

As a physician and surgeon of twenty-five years' experience it is my considered judgment that men now in medical school should be deferred as long as they pass the required grades in college in order that the needs of society in the years to come will be fully met. If no premedical students stay in school it might have a serious effect on the health of this country because of the lack of students graduating four or five years hence. The Army now has absorbed a large number of physicians to the extent that should an epidemic occur it might mean that lives would be lost because there would be a shortage of physicians. There are some four thousand physicians who die each year in the United States.

It seems imperative, Mr. President, that the country take steps to safeguard its future. If the present rule of inducting premedical students stands we will be in imminent danger of undermining the health of this country.

Other countries, including Russia, England and Canada, have recognized the problem and are keeping these premedical students in school. There are only about six thousand premedical students. Surely they would be of more service to the country as trained medical men than serving in the infantry or some other branch of the military. If they are taken from school it may well cripple the vital affairs of science, and the country would lose their medical service. It certainly would not guarantee a safe future for science and for the citizens of the country.

Under the present ruling the draft boards are not permitted to consider a premedical student as exempt from military service.

I am appealing to you and to General Hershey because I feel it is imperative that we not make the blunder of permitting such a drastic regulation to continue in force and thus deprive this country of adequate medical care in the future.

Respectfully yours,
A. L. MILLER, M.C.
Fourth District, Nebraska.

CC: Major General Lewis B. Hershey,
Selective Service Commission,
Washington, D. C.

The President's reply on July 5 was:

I have given careful thought to your letter of June 16 which you asked that I review the Selective Service order which does not permit the deferment of premedical students beyond July 1.

No one is more keenly conscious than I am of the need of maintaining the health of the nation and of making sure that we have an adequate supply of doctors. But in this war the need of the armed forces for young, vigorous men must also be given thorough consideration. The Army and the Navy have presented that need in urgent terms as essential to the winning of the war.

The Inter-Agency Committee on Deferments, which was formed some months ago to advise the Director of Selective Service on deferment of men under 26, gave careful consideration to the case of premedical students. The committee included representatives of all governmental agencies interested in manpower. I am told that this committee recommended that there be no deferment for premedical students who are not in medical school by July 1 of this year.

The committee, I am advised, took into account the fact that none of these premedical students could be of service in the practice of medicine prior to 1948, and that many of them would never practice medicine. The committee also gave attention to the fact that young men who do not come up to the exacting physical standards of the armed forces, as well as young women, are available to become premedical students.

As for the future supply of doctors, we must always bear in mind the ex-servicemen, a considerable number of whom will unquestionably desire to begin the study of medicine. As you know, there are many young men who have served their country in the armed forces and have already been discharged from further service. These men, and the far larger number later to be demobilized, must be given every opportunity in the way of education and training. I am told that the medical colleges are particularly interested in promoting medical education of well qualified ex-servicemen. This plan by the medical colleges in behalf of ex-servicemen has my hearty support.

For these reasons, after thorough consideration, I am unwilling to overrule the recommendation of the Inter-Agency Committee on Deferments in regard to premedical students or to instruct the Director of Selective Service to rescind the ruling that he made when he adopted the committee's recommendation.

I fully appreciate your keen interest in this important subject.

FRANKLIN D. ROOSEVELT

MISCELLANEOUS

ESTABLISHED VETERANS REHABILITATION CENTERS

The Office of War Information recently announced that rehabilitation centers will be established at colleges and universities throughout the United States to provide job counseling and to arrange for vocational training and rehabilitation of disabled veterans of the present war. Brig Gen Frank T. Hines, administrator of veterans affairs and administrator of the retraining and reemployment administration of the Office of War Information, stated that arrangements have been completed for the opening of the first of the proposed centers at the College of the City of New York. Additional centers in the various states will be selected from time to time. Eligible veterans who apply for vocational rehabilitation under the Veterans Administration program will have the assistance of the best qualified vocational counselors in the country at no cost to themselves. The Veterans Administration will provide transportation to the centers, which will be near veterans' homes, meals and comfortable quarters at the centers and medical service at the centers or during subsequent job training periods. Objective aptitude tests will be given the former servicemen to determine their abilities and interests and fit them into the occupations in which they are most likely to succeed. There will also be professional advice on selecting jobs.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service.

(Continuation of list in THE JOURNAL, July 1, page 639)

ILLINOIS

Methodist Hospital of Central Illinois, Peoria. Capacity, 240 admissions 5701. Dr. C. S. Woods, Superintendent (interns, October 1).

MICHIGAN

St. Lawrence Hospital, Lansing. Capacity 30 admissions 6897. Sister M. Assisium, Superintendent (interns).

OHIO

Mercy Hospital, Canton. Capacity 265 admissions 8361. Sister M. Euphrasia, Superintendent (interns).

WEST VIRGINIA

Ohio Valley General Hospital, Wheeling. Capacity 330 admissions 5069. Mr. J. S. Fuik, Superintendent (2 interns, October 1).

COMMUNITIES IN NEED OF PHYSICIANS

The U. S. Public Health Service, Washington, D. C., has recently advised that the program authorizing the relocation of physicians and dentists under Public Law 216, which became operative Dec. 23, 1943, has been terminated by Congress effective June 30, 1944. For those communities which have contributed their share of relocation expense and for which physicians or dentists have been contracted, the arrangement will be carried out according to the terms of the contract, from funds obligated for that purpose. Those communities which have submitted their checks for \$300 and for which it has been impossible as yet to locate a physician or dentist will have their monies refunded promptly.

PRICE OF PENICILLIN

Because of many inquiries regarding the maximum price of penicillin now available to civilian hospitals, the Office of Price Administration stated recently that considerable variation in the maximum price of that material exists at the present time. The OPA pointed out that actual selling prices have declined during the last year as production has become greater. One seller's price to civilian hospitals is \$3.15 per hundred thousand O. N. D. units. Since some sellers are supplying the U. S. government at a price much less than this, the OPA said it is reasonable to expect further reductions in the price to civilian hospitals.

PUBLIC HEALTH UNDER HITLER

Owing to present circumstances the figure of tuberculosis victims is continuously increasing, according to Vichy Home Service of March 10, 1944 (France). On Dec. 31, 1938 about 300,000 people suffered from the disease. The figure is now estimated at about 500,000, that is, between 10 and 12 per thousand of the total population. French antituberculosis facilities are unfortunately inadequate. There are some 1,000 welfare centers, 33,000 beds in sanatoriums, 16,000 in preventive centers and 12,500 in special hospitals. It is at present impossible to extend these facilities. The spread of the disease and the means available to fight it had led Dr. Grasset to draw up a rational plan. Its main principles are that tuberculosis is a disease which develops rapidly, so that there must be no delay in diagnosis and that patients who no longer require special treatment should not crowd specialized clinics. Surgeries have to examine patients and make a precise diagnosis within eight days. The patient is then taken to a specialized hospital center, where he is kept under observation for a few weeks and sent to the most suitable place of cure. If the disease is not contagious he is sent to a healthy locality, which may be a prevention center or even his own home. Otherwise he is sent to a sanatorium. Incurable and chronic patients on leaving the sanatorium, are taken to hospitals and curative centers. Clinics may reserve a certain number of beds for patients when there is no danger of their spreading the infection. Patients who have recovered are under observation from special centers, mainly attached to antituberculosis surgeries. Another problem, concerning the resettlement of workers who have recovered, is under consideration and the national company of French railways and the social insurances national institute of hygiene have already achieved a partial solution.

In the Jan. 1, 1944 *Deutsche Arzteblatt* (Germany), an article on diabetes and the wartime food supply by Dr. H. A. Heinsen, head of the University Clinic Giessen, concludes "To sum up, we can state that on the whole and with relatively few exceptions it has been quite possible to get our sufferers (from diabetes) to adapt themselves to the normal rations without any considerable extra rations. We should try to do this with every diabetic patient at least while the war is on. The question whether after the war, when presumably the consumption of fats and meat of the diabetic too will considerably increase, the very high carbohydrate contents of wartime rationed food are in all cases advisable must for the present remain unanswered."

According to the *Deutsche Arzteblatt* of January 1 (Germany) during the days of the Russian winter there has been a great increase of ecthyma vulgare, which occurs particularly on the calf. It is so frequent that a special name has been given to it. The simultaneous symptoms of a swelling, inflammation and edema, always on the calf, are characteristic of this disease which has become known as "Russische Unterschenkelentzündung." The presence of lice and the effect of scratching play an important part, and delousing is essential if a permanent cure is to be effected, as otherwise new swellings will constantly occur.

I. oltischer Beobachter, Vienna edition, February 22 (Germany), states that it is particularly important to supply the doctors with the necessary instruments. In order to be able to direct the production of these instruments more strictly, the Central Committee for Ironware, Tinware and Metalware has issued a new order according to which producers of doctors', dentists' and veterinarians' instruments and implements may manufacture and deliver these articles only if they hold the necessary permits issued by the central committee. No permit is required to carry out repairs to instruments.

An illegal medical publication in France appeals to doctors not to comply with the wish of the German occupying authorities, who desire to send 5,000 French doctors to Germany, according to *Stenka Dagbladet* of February 15.

ORGANIZATION SECTION

THE SERVICEMEN'S READJUSTMENT ACT OF 1944

An Abstract Prepared by the

Bureau of Legal Medicine and Legislation,
American Medical Association, Chicago

The G. I. Bill of Rights (S. 1767) was approved by the President on June 22 as Public Law 346. Seventy-Eighth Congress. It contains six titles.

TITLE I

Title I deals generally with hospitalization claims and procedures, aid by veterans' organizations and the review of discharges or dismissals from the armed forces.

It declares the Veterans' Administration to be an essential war agency, entitled to priorities second only to the War and Navy departments, such priorities so far as they relate to materials being extended to any state institution to be built for the care or hospitalization of veterans.

It authorizes an appropriation of \$500,000,000 for the construction of additional hospital facilities for veterans and sanctions agreements between the Administrator of Veterans Affairs and the Secretaries of War and Navy for the mutual use or exchange of use of hospital facilities.

It provides for the detail of commissioned, appointed or enlisted personnel from the armed forces to the Veterans Administration for periods not extending beyond six months after the termination of the war. It contemplates procedures to assure veterans of an opportunity to file claims for benefits.

It makes available adequate training in the use of prosthetic appliances in a service or a Veterans Administration hospital "or by outpatient treatment, including such service under contract."

It sets up machinery for the review of certain discharges or dismissals from service other than discharges by reason of the sentence of a general court martial.

TITLE II

Title II provides a program for the education of veterans following separation from service.

Eligibility for Benefits.—Persons who served in the active military or naval services on or after Sept. 16, 1940 and prior to the end of the war for the prescribed length of time and who shall have been released or discharged under conditions other than dishonorable will be entitled to the benefits of this title.

Veterans must have served ninety days or more or must have been released or discharged from active service by reason of an actual service incurred injury or disability. The ninety days of required service must be in addition to a (a) any period in which the person was assigned for a course of educational training under the Army specialized training program or the Navy college training program which course was a continuation of his civilian course and was pursued to completion, or (b) any period served as a cadet or midshipman at one of the service academies.

An otherwise eligible veteran over 25 years of age must show that his education or training was impeded, delayed, interrupted or interfered with by reason of his entrance into service in order to qualify for the additional education or training made available under this title. A veteran 25 years or younger is not required to make any such showing. His education or training is presumed to have been impeded, delayed, interrupted or interfered with.

An otherwise eligible veteran will be entitled too to a "refresher or retraining course" if he so desires.

Onset and Termination of Courses.—A course must be initiated not less than two years after either the date of the veteran's discharge or the end of the war, whichever is later. No education or training will be afforded beyond seven years after the end of the war.

Length of Courses.—An eligible veteran will be entitled to education or training or a refresher or retraining course for a period of one year, or the equivalent thereof in continuous part time study, or for such lesser time as may be required for the course of instruction chosen by him.

On completion of the one year course, other than a refresher or retraining course, the veteran will be entitled to an additional course not to exceed the time he was in service after Sept. 16, 1940 and before the end of the war and exclusive of any period he was assigned for a course of education or training under the Army specialized training program or the Navy college training program, which course was a continuation of his civilian course and was pursued to completion, and exclusive of any period he was assigned as a cadet or midshipman at one of the service academies.

The total period of education or training may not exceed four years.

Educational Institutions.—The veteran may select any approved institution to attend which will agree to accept or retain him. For reasons satisfactory to the Administrator of Veterans Affairs the veteran may change a course of instruction. If the progress of the veteran is unsatisfactory, the Administrator may terminate the course.

A list of approved institutions will be established in the following manner:

(1) The Administrator of Veterans' Affairs will be required from time to time to secure from the appropriate agency of each state a list of educational and training institutions including industrial establishments which are qualified and equipped to furnish education or training, including apprenticeship and refresher or retraining courses.

(2) the Administrator will be authorized to add additional institutions to such lists which in his judgment are qualified to participate in the program, and

(3) the institutions designated by the several appropriate state agencies plus the institutions designated by the Administrator himself "shall be deemed qualified and approved to furnish education and training to such persons as shall enroll under this part."

Educational or Training Institutions Defined.—The term "educational or training institutions" is defined to include

all public or private elementary, secondary and other schools furnishing education for adults, business schools and colleges, scientific and technical institutions, colleges, vocational schools, junior colleges, teachers' colleges, normal schools, professional schools, universities and other educational institutions and shall also include business or other establishments providing apprentice or other training on the job, including those under the supervision of an approved college or university or any state department of education or any state apprenticeship agency or state board of vocational education or any state apprenticeship council or the Federal Apprenticeship Training Service established in accordance with Public Number 170, Seventy-Fifth Congress or any agency in the executive branch of the federal government authorized under other laws to supervise such training.

Payment to Educational or Training Institutions.—The Administrator will pay to each institution for each veteran enrolled in a course of education or training (1) the customary tuition and (2) such laboratory, library, health, infirmary and other similar fees as are customarily charged.

The Administrator may pay for books, supplies, equipment and other necessary expenses, exclusive of board, lodging, other living expenses and travel, as are generally required for the successful pursuit and completion of courses by other students.

Payments by the Administrator may not exceed, with respect to any veteran, the sum of \$500 for "an ordinary school year."

Maintenance Allowances.—While enrolled in and pursuing a course, a veteran will be paid a subsistence allowance of \$50 a month if without dependents and \$75 a month if he has a dependent. Such a person attending a course on a part time basis and a person receiving compensation for productive labor performed as a part of their apprentice or other training on the job at institutions, business or other establishments will be entitled to receive such lesser sums, if any, as subsistence or dependency allowances as may be determined by the Administrator.

Rehabilitation of Veterans Entitled to Educational Benefits.—Any veteran entitled to vocational rehabilitation under Public Law 16, Seventy-Eighth Congress, who is also entitled to educational training under the Servicemen's Readjustment Act of 1944, may elect which benefit he desires.

Federal Control Over Educational Institutions.—This title provides that:

"No department, agency or officer of the United States, in carrying out the provisions of this part, shall exercise any supervision or control, whatsoever, over any state educational agency, or state apprenticeship agency, or any educational or training institution."

Excepted from the foregoing proscription are federal educational and training institutions over which federal jurisdiction is authorized by existing law.

Utilization of Existing State and Federal Facilities and Services.—The Administrator of Veterans' Affairs will be authorized to administer title II and must, so far as he finds it practicable, utilize existing facilities and services of federal and state departments and agencies on the basis of mutual agreements with them. He may promulgate rules and regulations necessary to carry out the purposes of the title.

Vocational Guidance for Beneficiaries.—The Administrator may arrange for the educational and vocational guidance of beneficiaries undergoing courses under this title. He may make available information as to the need for general education and for trained personnel in the various crafts, trades and professions, utilizing information, to the extent practicable collected by other federal agencies.

Medical and Hospital Care for Beneficiaries.—The appropriations made available to the Veterans Administration for the medical treatment and hospitalization of veterans generally are made available for persons undergoing courses under the title.

Books, Supplies and Equipment.—Any books, supplies or equipment furnished a veteran will be considered as having been released to him. If because of fault on his part a veteran fails to complete his course he may be required to return any books, supplies or equipment not actually expended or to pay the reasonable value thereof.

TITLE III

Title III relates to loans for the purchase or construction of homes, farms and business property. It sets up machinery whereby the Veterans Administration will guarantee loans made to veterans, provided the loans are to be expended for specified purposes. Those purposes are:

(1) The purchase, construction, alteration, repair or improvement of property to be occupied by the veteran as his home, or the payment of delinquent indebtedness, taxes or special assessments on residential property owned by the veteran and used by him as a home;

(2) the purchase of land, buildings, livestock, equipment, machinery, or implements, or the repair, alteration or improvement of any buildings or equipment, to be used in farming operations conducted by the veterans; and

(3) the purchase of any business, land, buildings, supplies, equipment, machinery, or tools to be used by the applicant in a gainful occupation, other than farming.

The aggregate amount guaranteed by the Veterans Administration may not exceed \$2,000 in a particular case nor 50 per cent of the loan negotiated for the purposes indicated. Provision is made for the guaranteeing of a second loan under specified conditions.

Application for the guaranty of a loan must be made within two years of separation from service or within two years of the termination of the war, whichever is later, but may not be filed later than five years after the war.

Interest for the first year on the guaranteed part of the loan will be paid by the Veterans Administration, and thereafter the interest on the guaranteed part of the loan may not exceed 4 per cent. The guaranteed part of the loan is to be repayable in twenty years.

TITLE IV

Title IV contemplates a job counseling and employment placement service for veterans to be operated under the United States Employment Service with the cooperation and assistance of the Veterans' Placement Service Board, to consist of the Administrator of Veterans' Affairs as chairman, the director of the National Selective Service System, and the administrator of the Federal Security Agency. This board will determine all matters of policy relating to the administration of the Veterans' Employment Service of the United States Employment Service.

It is contemplated that the United States Employment Service will assign to each state a veterans' employment representative who, in cooperation with the public employment service staff in the state, will be functionally responsible for the supervision of the procedures undertaken to effect the employment of veterans.

TITLE V

Title V provides readjustment allowances for former members of the armed forces who are unemployed.

Readjustment allowances will be paid, subject to the conditions set forth in detail in the title, for each week of unemployment, not to exceed a total of fifty-two weeks, which (1) begins after the first Sunday of the third calendar month after June 22, 1944 and (2) occurs not later than two years after separation from the service or the end of the war, whichever is the later date. No allowances will be paid for any week commencing more than five years after the end of the war.

The number of weeks of allowances to which a veteran will be entitled, subject to the fifty-two week limit, will be determined by the length of service of the veteran.

The allowance payable will be \$20 a week less that part of the wages paid to the veteran for such week in excess of \$3.

To be eligible for readjustment allowances, a veteran must (a) reside in the United States, (b) be completely unemployed or, if partially unemployed, must not have received wages in excess of \$23 a week, (c) be registered with and reporting to a public employment office and (d) be able to work and available for suitable work, but no veteran will be considered ineligible in any period of continuous unemployment because of inability to show that he is able to work and available for suitable work if such failure is due to an illness or disability which occurs after the commencement of such period.

An otherwise eligible veteran who is self employed for profit in an independent establishment, trade, business, profession or other vocation will be eligible for readjustment allowances if he has been fully engaged in such self employment and if his net earnings have been less than \$100 in the previous calendar month. Such a veteran will be entitled to receive the difference between \$100 and his net earnings for such month, subject to the \$20 a week limitation and the time limit applicable to unemployed veterans generally.

TITLE VI

Title VI contains general administrative and penal provisions.

WASHINGTON LETTER

(From a Special Correspondent)

July 10, 1944.

The Public Health Service Act

An attack on the tuberculosis problem on a national scale is provided for in the Public Health Service Act (signed by the President on July 3). The act streamlines the administration of the Public Health Service, bringing together in compact and orderly arrangement substantially all existing laws affecting the service, eliminating many outmoded laws and effecting revisions dictated by operating experiences. Its new provisions include authority to make grants-in-aid to research institutions for any disease, just as the National Cancer Act of 1937 provides for cancer research; expansion of the federal-state cooperative public health programs, and establishment of a national tuberculosis control program patterned after the venereal disease control program.

The provisions of the bill for investigation and control of tuberculosis are understood to be incorporated in the Public Health Service Act.

The new law retains all the important duties of the Public Health Service which have been granted to it by Congress in legislation enacted in the past fifty years, such as medical and hospital care of American Merchant Marine seamen, the United States Coast Guard and other federal beneficiaries, the National Quarantine Service, scientific research, control of biologic products, care of leprosy patients and narcotic drug addicts and assistance to the state and territorial health departments. The purpose of the tuberculosis control bill was to enable the Surgeon General of the Public Health Service to seek more effective measures of prevention, treatment and control of tuberculosis, to assist states, counties, health districts and other political units of states in establishing and maintaining such measures and to control the spread of tuberculosis in interstate traffic.

The Public Health Service Act of 1944 as approved by the House and Senate makes it possible to extend a direct attack on tuberculosis. The act authorizes the establishment of a tuberculosis control program in the Public Health Service with the responsibility of administering grants-in-aid to the state health departments, and of conducting demonstrations and research leading to eradication of the disease. The act raises the ceiling of federal appropriations for grants-in-aid to the states under title VI of the Social Security Act from \$11,000,000 to \$20,000,000 annually. It is explained in Washington that the Public Health Service will now be able to recruit and commission in the regular corps younger officers who otherwise would serve as interns in the marine hospitals. The act also permits commissioning of qualified personnel in professions other than medicine, dentistry and engineering—specialists in such fields as entomology, chemistry and zoology.

Under provisions of the new law, the Nursing Corps of the Public Health Service may be commissioned just as the nurses of the Army and Navy are commissioned. The nurses not only staff the hospitals, dispensaries and treatment centers operated by the Public Health Service but also act as public health nursing consultants to state health departments and administer the nurse education program. Other sections of the new law will give to commissioned personnel of the Public Health Service in wartime substantially the same benefits and privileges as are provided for officers of the Army and Navy. The service now includes four major administrative units in its organization. They are the Office of the Surgeon General, the National Institute of Health (Bureau of Scientific Research), the Bureau of State Services and the Bureau of Medical Services. The staff of the Surgeon General now includes a deputy surgeon general and three assistant surgeons general in charge of the three bureaus. In addition, staff officers with the rank of Assistant Surgeon General are assigned to the administration of dental and sanitary and engineering activities respectively. The medical director of the United States Coast Guard has the rank of Assistant Surgeon General on the staff of the Surgeon General.

The Public Health Service was established in 1898 as an agency to provide medical and hospital care for members of the

American Merchant Marine. It is one of the oldest of federal agencies and has been a constituent of the Federal Security Agency since 1939. The service was 68 years old when Pasteur demonstrated germ causation of disease. It was the first federal agency authorized to undertake scientific research on diseases of mankind and conditions propagating their spread. Acts of Congress in 1878, 1890, 1893 and 1906 gave it authority to prevent introduction of epidemic diseases into this country from abroad and to prevent the interstate spread of communicable diseases. Fundamental reorganization laws expanding the functions and strengthening the administration of the service have been enacted several times. In 1889 it was organized along military lines, when provision was made for establishment of a corps of commissioned officers with grades, ranks and rates of pay like those of the medical corps of the U. S. Army and Navy. In 1902 the service was given responsibility for the control of biologic products (vaccines, serums, toxoids and the like). This law required that the service establish standards for their manufacture and that manufacturers be licensed by the service for the sale of biologic preparations in interstate commerce.

Scientific research has developed from a small laboratory to a major bureau, the National Institute of Health, which occupies modern laboratories in Bethesda, Md. Authorized by Congress in 1930 to extend research activities to any disease or condition affecting the people, the institute conducts investigations on infectious diseases, cancer, zoology, physiology and industrial toxicology. The National Cancer Institute, established by Congress in 1937, is a major division of the National Institute of Health.

From earliest days, the Public Health Service has cooperated with state and local health agencies and with voluntary organizations. In 1935 title VI of the Social Security Act placed administration of the federal-state cooperative public health program in the Public Health Service. This involves the allotment of grants-in-aid to state health departments, the provision of consultant services and technical assistance to the states.

Tuberculosis Division

The establishment of a tuberculosis control division in the Public Health Service was announced on July 10 by Surg. Gen. Thomas Parran. Dr. Herman E. Hilleboe, in charge of the Public Health Service tuberculosis control activities since 1942, was named chief. The tuberculosis division will be within the Public Health Service Bureau of State Services, headed by Dr. L. R. Thompson. Dr. Parran's order was approved by Paul McNutt, Federal Security Administrator.

The functions of the new division will be (1) developing and effecting means for the prevention, treatment and control of tuberculosis; (2) assisting states, counties, health districts and other political subdivisions of the states in establishing and maintaining adequate measures for the prevention, treatment and control of such diseases; (3) preventing and controlling the spread of tuberculosis in interstate traffic and any other activities with respect to the prevention, treatment and control of tuberculosis which may be authorized to be performed by the Public Health Service.

The sum of \$10,000,000 was authorized in the act of 1944 for this new work and will be available as soon as funds are appropriated.

Dr. Hilleboe was born in West Hope, N. D., in 1905 and was educated at the University of Minnesota Medical School, where he received the B.S. and M.D. degrees, and at the Johns Hopkins School of Hygiene and Public Health, where he received a Master of Public Health degree. He is a member of a number of local, state and national societies and health organizations, including the National Tuberculosis Association, on whose board of directors and Medical Research Council he serves. He entered the Public Health Service as a paid assistant surgeon in the regular commissioned corps in 1931, and he made special studies of tuberculosis control in the Public Health Service and Scandinavian countries, France and England in 1939. When he returned from England he was made chief of the medical unit of the Minnesota Division of Social Hygiene. He served there till 1942, when he was appointed medical officer in charge of the Public Health Service tuberculosis control section of the state relations division. He was promoted to the rank of senior surgeon in 1943.

MEDICAL ECONOMIC ABSTRACTS

OREGON PHYSICIANS' SERVICE

Medical care on the job is the responsibility of the employer under the State Industrial Accident Commission. Recently this responsibility has been extended to cover occupational disease. Originally this care was furnished largely by individual plant systems or by entering into a medical contract. For some years a high percentage of such contracts has been with medical societies, principally with the Oregon Physicians' Service.

The Oregon Physicians' Service was incorporated as an Oregon corporation on Dec. 6, 1941, although no business was transacted until June 1942. At the time of incorporation a number of local medical service bureaus had been established by groups in different parts of the state and with the approval of the various medical societies. There was no existing organization, however, to take care of prepaid medical contracts covering migratory workers or groups in sections of the state lying between the local bureaus, and the first function of the Oregon Physicians' Service was to fill these gaps in coverage wherever asked to do so. Many of the local bureaus have since merged with the Oregon Physicians' Service.

The original capital was provided by the Oregon State Medical Society, which, under a trust agreement, purchased the entire issue of Oregon Physicians' Service voting stock and placed it in the hands of eleven trustees named by the council.

In general, the type of medical and hospital contract written by the Oregon Physicians' Service conforms to the usual hospital association contract that has been written in Oregon for several years to cover off the job illness. It is a contract entered into with the employer, who acts on behalf of and with the consent of the employee. The principal services offered are medical and surgical care, hospital care, special nursing, x-ray and physical therapy, ambulance and limited dental care. No prescriptions are provided. Limitations are placed on the care of certain types of cases; also a maximum of one year on medical care and six months of hospital care on any 1 case. This standard type of contract is offered to employed persons only at the rate of \$2.50 per month. Approximately 17,600 persons were under such contracts on June 30, 1943.

Special contracts have been written with the two Kaiser shipyards in Oregon, which provide that the Oregon Physicians' Service shall cover medical costs only. Hospitalization of the shipyard employees is provided by the Blue Cross plan. The total premium for this coverage is 60 cents per week, of which the Oregon Physicians' Service receives 45 cents for the medical coverage; 43,100 workers were under the "M & H plan" on June 30, 1943.

The Oregon Physicians' Service also entered into an agreement with the Farm Security Administration to provide medical and hospital care to families eligible for standard loans under its settlement program in the Snake River area of eastern Oregon. This coverage was first written for an annual rate of \$40 per family, but this was increased to a \$50 rate in 1943 to provide sufficient funds to warrant continued participation by the Oregon Physicians' Service staff members. The limited experience had with this type of coverage is inconclusive, but without some selection of risks it is evident that a broad medical and hospital coverage for families will be rather unsatisfactory to the physicians for at least the first year. These families were unable to pay for their medical care as private patients prior to their coming under the Farm Security Administration program (many of them had come from areas of extreme under-privilege) and hence there was an unusual amount of needed medical service, often involving surgery, that required attention whenever later sickness arose in these people. It is anticipated that the coming year will produce improved returns to the participating physicians.

The total number of persons under coverage by the Oregon Physicians' Service at the end of June 1943 was approximately 83,000, with an additional 22,000 covered by its affiliates, making a total of about 105,000 under coverage directly supervised by organized medicine out of a total prepaid coverage in the state estimated to be some 150,000 people.

The physicians on the staff of the Oregon Physicians' Service number 678 in active civilian practice; an additional 173 are in military service. This total of 678 represents 95 per cent of the active membership of the Oregon State Medical Society and 85 per cent of all licensed medical practitioners in Oregon. The only requirement for admission to the Oregon Physicians' Service staff is that the physician be a member of the state medical society or eligible therefor.

Wherever an approved medical service bureau is already in operation and wishes to preserve its separate entity, the Oregon Physicians' Service endeavors to assist it in any feasible manner, and a genuine and friendly cooperation has been built up between such bureaus and the Oregon Physicians' Service.

The component local societies largely govern the activities of the Oregon Physicians' Service in their respective districts through their own supervisory committees. If desired, each district may establish a separate "pool," so that the Oregon Physicians' Service contracts written in that district will inure to the benefit of the staff physicians in that area; six such pools were in operation on June 30. Those districts not choosing to localize their Oregon Physicians' Service contract practice have been grouped together in a "statewide" pool.

The Oregon Physicians' Service does not enter any county until prior authorization has been received from that county society. All but one of the counties of Oregon (other than the five previously named which have independent approved organizations of their own) have requested the Oregon Physicians' Service to enter into contracts with their employed groups, and mergers have been completed or are under way.

The rate of expansion in Oregon Physicians' Service activities is only partially reflected in the income figures. During the twelve months, 489 contracts were acquired either by merger with existing medical service bureaus or by new enrolments. These contracts represented a net increase of 48,800 members, 40,000 of whom were shipyard employees.

Gross earned income for the year was \$800,200. Of this amount \$576,973 was expended on direct medical and hospital care of patients, \$104,595 was expended for first aid service which directly benefited the subscribers and \$118,128 was expended for administrative expenses. It is noteworthy that member physicians received 53.2 per cent of income in the form of fees for services, and an additional 5.7 per cent was paid to nonmember physicians handling emergency cases; the medical profession thus received 58.9 per cent of each revenue dollar. Administrative costs amounted to 14.8 per cent of earnings, a relatively low percentage considering that the first year of any business calls for abnormally heavy costs in this category.

The huge influx of war industries in the metropolitan area of Portland has created a number of special problems in the medical field. One such problem is the Vanport City Housing Project, designed to accommodate 40,000 persons. As the majority of the workers living in Vanport are employees of the Kaiser shipyards, the Oregon Physicians' Service was asked to operate the hospital erected there as a part of its function of providing medical care to the Kaiser employees. The hospital was opened on a limited scale on Aug. 1, 1943 and is still unable to admit certain types of cases because of delays in receiving certain necessary equipment. This equipment is on order and is expected to be installed and in use in a few weeks. The hospital can then render adequate service to Vanport City.

The heavy concentration of workers in the Kaiser yards made it necessary to operate fairly elaborate first aid stations in those yards. Over 2,000 persons are treated daily at these first aid stations. The Oregon Physicians' Service employs a staff of 150 at these stations, including thirteen full time salaried physicians. The sizable cost of operating these stations is divided between the Oregon Physicians' Service and the State Industrial Accident Commission in the ratio of treatments rendered for industrial and nonindustrial cases in which reports are made to the stations. Approximately 63 per cent of all cases are industrial injuries; hence the commission bears that proportion of the first aid station costs.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. James W. MacQueen, medical director of the Hillman Hospital, Birmingham, has been appointed in charge of the Hillman and Jefferson hospitals. Dr. MacQueen, who had been superintendent of the Hillman Hospital, was named to the new position when both county hospitals were merged. —Dr. Elisha M. Moore, Livingston, has been appointed health officer of Autauga County.

CALIFORNIA

William Greulich Named Professor of Anatomy.—William Walter Greulich, who received his doctor of philosophy degree at Stanford University in 1934, has been appointed professor of anatomy there, effective at the start of the summer quarter. Since 1940 Dr. Greulich has been professor of physical anthropology and anatomy and director of the Brush Foundation at Western Reserve University School of Medicine, Cleveland.

New School of Veterinary Medicine.—The University of California plans to establish a school of veterinary medicine at Davis. Appropriation of \$500,000 has been made by the legislature for the project and, according to *Science*, an additional \$500,000 is expected from the postwar building funds provided by the legislature. The department will be set up in the college of agriculture, the faculty to be drawn not only from the department of veterinary science but from other departments, including the department of agriculture and the medical school.

ILLINOIS

Portrait of Dr. Carlson.—A feature of the alumni banquet of Augustana College, Rock Island, was the presentation to the college of a portrait of Dr. Anton J. Carlson, emeritus professor of physiology, University of Chicago School of Medicine. The portrait is the work of Carl Tolpo. Dr. Carlson graduated at Augustana in 1898.

Chicago

John Mannix Named to Chicago Plan for Hospital Care.—John R. Mannix, formerly executive director of Michigan Hospital Service, Detroit, recently became executive director of the Chicago Plan for Hospital Care.

Dentist Leaves Estate to Blind.—Charles J. Tibbets, dentist, who died May 23, bequeathed \$1,000 of his \$25,000 estate to Seeing Eye, Inc., Morristown, N. J., and the remainder to the American Foundation for the Blind, Inc., New York.

Dr. Routley Delivers Root Lecture.—The William W. Root lecture of Alpha Omega Alpha was delivered in Chicago, June 15, by Dr. Thomas C. Routley, Toronto, Ont., Canada, on "Newer Phases of Medical Education." At the meeting of the society in February, honorary membership was conferred on Norman T. Kirk, Surgeon General of the Army, Ross T. McIntire, Surgeon General of the Navy, and David N. W. Grant, Air Surgeon.

Physician Sentenced in Stolen Car Case.—Dr. Lawrence T. Browning was sentenced to three years in prison June 22 by Federal Judge Luther M. Swygert in South Bend, Ind., newspapers report. When arrested the physician gave his address as 634 South State Street, Chicago. He was said to be arrested on a charge of driving a stolen automobile across the state line. Newspapers reported that agents of the federal bureau of investigation arrested him after he tried to sell stolen medical equipment and charged that he had driven two stolen automobiles across state lines. On June 14 he was placed on probation. Four days later he was arrested again in Valparaiso, Ind. He admitted that he had stolen another car in Chicago. He was sentenced for driving this car to Indiana and for driving another stolen car from South Bend to Niles, Mich.

KENTUCKY

Personal.—Dr. Charles E. Youmans has been appointed medical superintendent of the State Institution for the Feeble-minded, Frankfort, to succeed Dr. Lynn D. Adams, resigned. —Dr. Don E. Wilder, Grayson, recently resigned as health officer of Carter County.

New Health Center Dedicated.—A new building housing the city-county health center of Hopkinsville and Christian County was dedicated June 8. The unit was erected with the assistance of \$60,000 contributed by the government. Dr. Philip E. Blackerby, Louisville, state health commissioner, gave the principal address. The unit is under the direction of Dr. Robert H. English.

The Gross Lecture.—Dr. Geza de Takats, associate professor of surgery, University of Illinois College of Medicine, Chicago, delivered the fifth Samuel D. Gross Lecture at the University of Louisville School of Medicine, May 23, on "The Causalgic State in Peace and War." The lectureship is sponsored annually by the University of Louisville chapter of Phi Delta Epsilon.

MARYLAND

New Officers of Medical Board.—Dr. Edward P. Thomas, Frederick, was on June 6 chosen president of the Board of Medical Examiners of Maryland and Dr. Erasmus H. Kloman, Baltimore, was named vice president. Dr. John T. O'Mara, Baltimore, was reelected secretary-treasurer. Dr. Edward M. Hanrahan Jr., Baltimore, was recently elected a member of the board to succeed Dr. Thomas R. Chambers, Baltimore, whose term expired.

Personal.—Elmer V. McCollum, Ph.D., professor of biochemistry at the School of Hygiene and Public Health of the Johns Hopkins University, Baltimore, has been elected a foreign member of the Swedish Academy of Sciences. —Dr. George W. Corner, director of the department of embryology, Carnegie Institution, Baltimore, was awarded the honorary degree of doctor of science during the recent commencement of the University of Rochester, N. Y.

Physician to Hold New Welfare Position.—On April 14 the board of estimates approved the establishment in the Baltimore Department of Welfare of a new position of assistant director of welfare for medical care. *Baltimore Health News* reports that a qualified physician will be selected for the position, subject to the regulations of the city service commission. After his appointment he will be designated, for liaison purposes, deputy commissioner of health in the city health department.

MASSACHUSETTS

Fellowships in Clinical Nutrition.—The Nutrition Foundation has awarded grants to Harvard Medical School, Boston, to support fellowships in clinical nutrition, effective through the years 1944, 1945 and 1946. The fund will be administered under the supervision of Dr. Fredrick J. Stare, assistant professor of biochemistry and nutrition. Two types of training are provided for by the fellowship fund: postdoctorate training in medicine and advanced training in medical nutrition for dietitians.

Alumni Activities at Boston University.—On April 30 the Alumni Association of Boston University School of Medicine brought out the first copy of a bulletin designed for alumni members in service. The publication was financed by the alumni association and will be issued once a year. At the annual meeting of the association on May 15 Dr. Eleanor B. Ferguson-Howard, Boston, who graduated in 1920, was chosen president, the first time in the history of the medical school that a woman has been elected to the office. She succeeds Dr. Clifton B. Leech, Providence, R. I. Other officers include Drs. Leon W. Crockett, Boston, and Roger M. Burgoyne, Winchester, vice presidents; Dr. Frank E. Barton, Newton, secretary, and Dr. Kenneth Christophe, Needham, treasurer.

MICHIGAN

Clifford Young Dies.—Clifford C. Young, D.P.H., Lansing, director of laboratories of the Michigan Department of Health since 1918, died June 5.

Ninety-Three Years of Age.—Dr. Homer P. Mix, Riverside, who was born in 1851 and who has practiced medicine for sixty-five years, is still practicing medicine and is considered the oldest practicing physician in the state. According to the *News-Palladium*, Dr. Mix, known as the "Old Timer," delivered a 12 pound daughter to a local family, June 20.

Property Available for Cancer Laboratory.—The Detroit Institute of Cancer Research has purchased from the Detroit Edison Company the Detroit Edison Club property at the northeast corner of St. Antoine and Frederick streets. It will remodel the two buildings there as a temporary cancer research laboratory and will make the grounds available as a playground for the children of the neighborhood. It was announced June 25. The site was chosen because it is on that of the proposed Medical Science Center of Wayne University, with which the institute

hopes to cooperate closely in cancer research. Eventually the buildings will be replaced with new structures. Dr. Rollin H. Stevens, Detroit, is president of the institute, which was established in November 1941.

MISSISSIPPI

New Officers of Hospital Association.—Dr. William H. Brandon, Clarksdale, was elected president of the Mississippi State Hospital Association at its annual meeting in Jackson in May, succeeding Dr. George E. Adkins, Jackson. Other officers include Dr. Henry Boswell, Sanatorium, vice president, and Miss Grace Golden, Vicksburg, secretary-treasurer. The society voted to hold its next annual meeting separate from the state medical association.

State Board Commended for Care of Public Health.—The Jefferson Davis County Committee of One Hundred, composed of civic minded Negro citizens of the county, recently paid tribute to the Mississippi State Board of Health and its director, Dr. Felix J. Underwood, Jackson, for the effective health program carried on for the benefit of all people. The letter acknowledging the tribute was sent to Dr. Underwood by A. L. Johnson for the Jefferson Davis County Committee. Mr. Johnson stated that his organization was "especially proud of the local staff because its members are thoroughbreds without exception, competent, efficient, devoted to duty and possessed with a keen appreciation of human personality." This agency, he said, is an endorsement of the American way of life and points the way for future action. The Committee of One Hundred is an organization for the general improvement of the conditions of the colored people in Mississippi.

NEW HAMPSHIRE

Dr. Frechette Returns as State Health Officer.—Alfred L. Frechette, surgeon, U. S. Public Health Service, who recently returned from Africa, was expected to resume his activities as state health officer July 1, according to the *New Hampshire Health News*.

NEW JERSEY

Dr. Arthur Richardson Joins Squibb Institute.—Dr. Arthur P. Richardson, professor and head of the department of pharmacology, University of Tennessee College of Medicine, Memphis, has been appointed head of the division of pharmacology of the Squibb Institute for Medical Research, New Brunswick, effective October 1. Dr. Richardson will succeed Dr. Harry B. Van Dyke, who has accepted an appointment as head of the department of pharmacology at Columbia University College of Physicians and Surgeons. Dr. Richardson graduated at Stanford University School of Medicine, San Francisco, in 1937. He subsequently served on the staff of Stanford, as fellow for the National Research Council at Johns Hopkins University and as a member of the faculty of the University of Tennessee College of Medicine.

Fined for Advertising Tuberculosis Cure.—Emile Carpentier, Hillsdale, has been penalized \$15,000 for violating the Federal Trade Commission order directing him to discontinue advertising a preparation as a cure for tuberculosis, the *New York Times* reported June 15. It was stated that the judgment was the largest ever ordered in a civil penalty suit brought by the department of justice for violation of the federal trade commission cease and desist order. According to the report, in February 1938 the commission directed Carpentier to discontinue representing that a product sold as "T. B. Compound" had therapeutic or remedial value. Three counts alleging separate violations of the order were filed in the U. S. District Court in Trenton and a maximum penalty of \$5,000 was imposed on each count. It was stated that Carpentier traded under the name of "Mrs. E. Carpentier."

Dr. Barkhorn Receives Ill Award.—On May 18 the Academy of Medicine of Northern New Jersey presented its Edward J. Ill Award to Dr. Henry C. Barkhorn for his many services to the academy. The citation accompanying the award identifies Dr. Barkhorn as a "man of wisdom and understanding, talented surgeon, eminent citizen." Dr. Barkhorn served as treasurer of the academy from 1922 to 1935. Since then he has been vice president, president, chairman of the public health and education committee and since 1942 chairman of the board of trustees. He was president of the Essex County Medical Society in 1930 and has been active in the functions of the state medical society, serving fourteen years as chairman of its publication committee. During the absence in service of the editor of the state medical journal Dr. Barkhorn has edited it in addition to the *Bulletin* of the Essex County Medical Society.

NEW YORK

Physician Observes Ninety-Third Birthday.—Dr. Frederick N. Winans, Franklin, recently observed his ninety-third birthday. Dr. Winans graduated at Columbia College College of Physicians and Surgeons in 1874.

Schools and Theaters Closed in Paralysis Ban.—On July 3 eight playgrounds were closed for one week by Dr. Leo M. Michalek, health officer of Lackawanna, as a precautionary measure against the spread of infantile paralysis, according to the *New York Times*. Four cases had been reported in the Lackawanna area, 2 in the city and 1 each in the villages of Blasdell and Hamburg. Dr. Richard G. Taylor, health officer of the town of Hamburg, ordered all motion picture theaters closed, it was stated.

Personal.—Dr. David W. Park resigned his position as superintendent of Potsdam Hospital, Potsdam, effective July 1, to become field representative of the American College of Surgeons. For the time being he will continue to live in Potsdam.—Dr. Leo J. Palmer, Elmira, has retired as superintendent of the Elmira reformatory hospital, a position he had held since Dec. 1, 1939.—Dr. David E. Fraser has been appointed health officer of Lyndonville, succeeding Lieut. Julius J. Laver, M. C.—Dr. John E. Wattenberg, a member of the Cortland Board of Education for five years, has been elected president of the board.—Dr. Willard H. Veeder, Rochester, has been appointed superintendent of the Craig Colony for Epileptics at Sonyea.

Advisory Council Named to Administer Workmen's Compensation Law.—On June 25, Governor Dewey appointed a state industrial council of nine members, reduced from fifteen, under a reorganization as a result of the state investigation into administrative aspects of the workmen's compensation law. The council's function is that of an advisory body to the state industrial commissioner on all matters relating to the department of labor, which, in turn, administers workmen's compensation. Under the reorganization act, which requires three representatives each for employees, employers and the medical profession, membership of the former council was terminated on June 1. The new unit includes employee and employer representatives. In addition, medical representatives listed are Albert W. Bailey, osteopath, Schenectady; Dr. Connie M. Guion, New York City, and Dr. Nathan B. Van Etten, Bronx. Dr. Guion and Dr. Van Etten are new appointees, the others having been members of the former council. The reorganization law provides that physicians on the council shall function also as a medical appeals unit which shall "consider all matters connected with the practice of medicine, prescribe rules for the medical practice committee, medical societies or boards investigating medical violations, and shall review charges for medical treatment and care (of injured workmen)," according to the *New York Times*.

New York City

Medical Veterans' Aid Fund.—Trustees of the Physicians Loan and Relief Fund of the Medical Society of the County of New York, under the direction of Dr. Nathan O. Ratnoff, have formed a Medical Veterans' Aid Fund. Returning members in need of economic assistance may borrow from this fund without interest to reestablish themselves in practice, train for a specialty or undergo suitable rehabilitation in the event of disability. Contributions to the fund will be accepted.

Dr. Cohn Made Member Emeritus at Rockefeller Institute.—Dr. Alfred E. Cohn, since 1920 a member of the Rockefeller Institute for Medical Research, has been made member emeritus of the institute, having reached the retirement age. Dr. Cohn graduated at Columbia University College of Physicians and Surgeons in 1904, joined the Rockefeller Institute in 1911, and became an associate member in 1914; he has been a member of the China Medical Board of the Rockefeller Foundation since 1934. Promotions on the scientific staff of the institute include those of Walther F. Goebel, Ph.D., from associate member to member and Dr. Robert F. Watson from assistant to associate.

Report Urges Revocation of Compensation Licenses for 119 Physicians.—Recommendations that 119 physicians lose the right to handle workmen's compensation cases for periods ranging from fifteen days to one year were contained in a report submitted June 23 to Edward Corsi, industrial commissioner, by the compensation boards of the Queens, Bronx and Westchester county medical societies. According to the *New York Times*, the boards passed on a total of 1,077 cases of medical men accused of participation in "kick-back rackets" and also suggested that 325 doctors be censured, 232 exonerated and the cases of 339, now in the armed services, be filed for future action. Additional hearings were recommended for

two others accused. All the doctors named by the boards have been notified of the recommended disposition, Mr. Corsi said, and have thirty days in which to file appeals before the Industrial Council of the State Department of Labor.

PENNSYLVANIA

Health and Human Relations.—The Pennsylvania Department of Health will sponsor a conference on health and human relations at State College, July 18-19. Among the topics to be discussed will be "How Science Dispels Many Misconceptions About Sex" and "Equitable Divisions of Responsibility in Sex Education Problems Between Teacher, Parent, Physician, Church, Community and State." Among the speakers at the meeting were Dr. Alexander H. Stewart, Harrisburg; Dr. Stanley P. Reimann, Philadelphia; Oscar Riddle, Ph.D., New York; Dr. George Lynde Gately, Boston; Erval R. Coffey, Assistant Surgeon General, U. S. Public Health Service, and Dr. William H. Perkins, Philadelphia.

Pittsburgh

Personal.—Dr. Thomas W. Cook has been appointed chief surgeon of the Pittsburgh Safety Department to succeed Dr. Daniel E. Sable, who retired to engage in private practice. The state medical journal reports that Dr. Sable in his thirty-four years in the position answered 60,000 fire alarms.

Physicians at Reunion of Johnstown Flood Association.—Dr. John D. Milligan, Pittsburgh, who will observe his ninety-third birthday July 31, and Dr. Elmer E. Wible, Homestead, formerly deputy coroner of Westmoreland County, attended the Pittsburgh meeting of the Johnstown Flood Correspondents Association on May 31. The group is made up of members who worked in various capacities during the Johnstown flood.

RHODE ISLAND

Industrial Meeting.—The Rhode Island Society of Industrial Physicians and Surgeons and the Rhode Island Industrial Nurses' Club met in joint session May 23 in Providence. Among the speakers were:

Louis Schwartz, medical director, U. S. Public Health Service, Occupational Diseases in Rhode Island Industries.

Dr. Chicago, The Meaning of Industrial Medicine.

Dr. Orlen J. Johnson, Council on Industrial Health, American Medical Association, Hospitalization and Cash Sickness Insurance Sponsored by Industry.

A feature of the meeting was a symposium on "Reconditioning of Disabled War Veterans and Their Assimilation by Industry."

State Medical Election.—Dr. John F. Kenney, Pawtucket, was chosen president elect of the Rhode Island Medical Society during its meeting in Providence May 24-25, and Dr. Elihu S. Wing, Providence, was installed as president. Dr. Fenwick G. Taggart, East Greenwich, was named vice president. Dr. Michael H. Sullivan, Newport, the outgoing president, spoke on "Changing Aspect of Medical Organization." Dr. Reginald Fitz, Boston, delivered the Charles V. Chapin Oration on "Forecast by Numbers." Among other speakers at the meeting were:

Comdr. Clarence C. Fuller (MC), Results in Treatment of 60 Cases of Malaria, and a Review of 100 Cases of Filariasis.

Dr. James R. Miller, Hartford, Conn., Planning for Medical Care.

Dr. Walter C. Alvarez, Rochester, Minn., Sick Headaches.

Dr. Justus B. Rice, New York, Malaria.

TEXAS

Training Center for Record Librarians.—To assist in current hospital problems, a training center for record librarians has been established at the John Sealy Hospital, University of Texas School of Medicine, both of Galveston, under the direction of Miss Margaret McArdle, R.R.L., who is in charge of the record library of the John Sealy Hospital.

State Medical Election.—Dr. Claude C. Cody Jr., Houston, was chosen president elect of the State Medical Association of Texas at its annual meeting recently. Dr. Herschel F. Connally, Waco, was installed as president. Other officers include Drs. Ralph G. Johnson, Newgulf, Elbert W. Wright, Bowie, and Herschel E. Wingham, McAllen, vice presidents. Dr. Holman Taylor, Fort Worth, is secretary of the association.

Survey of Health Facilities.—A survey of the medical education needs of the state of Texas will be carried out by a committee recently appointed by the board of regents of the University of Texas, the purpose of which is to determine the most appropriate way the university may serve the state in providing educational facilities for promoting the health of the citizens. The survey will include all parts of the state. Members of the committee include members of the board of regents,

the dean of the school of dentistry in Houston, Fred C. Elliott, Chauncey D. Leake, Ph.D., dean of the medical branch at Galveston, and Homer P. Rainey, president of the University of Texas.

News of Baylor University.—The John and Mary R. Markle Foundation recently awarded a grant of \$7,000 to Baylor University College of Medicine, Houston, to support the work of Allen D. Keller, Ph.D., on brain stem and related hypophyseal and cerebellar functions during the coming two years. Dr. Keller is professor of physiology and chairman of the department of physiology and pharmacology at the university. Major Carl T. Javert, M. C., lectured to the students and faculty on "Erythroblastosis Fetalis." Major Javert, who held conferences with obstetricians, pediatricians and pathologists, visited the school through a grant awarded by the H. E. Butt Foundation of Corpus Christi. New appointments to the school include those of Carroll A. Handley, Ph.D., Vermillion, S. D., to assistant professor of physiology and pharmacology; Dr. George W. Salmon, St. Louis, to assistant professor of pediatrics; Dr. Don W. Chapman, Iowa City, to instructor in the department of internal medicine, and Dr. William W. Coulter Jr., Kerrville, Texas, to instructor in the department of internal medicine. Miss Ella May Shackleford, formerly with the J. C. Oliver Memorial Research Laboratory, St. Margaret Memorial Hospital, Pittsburgh, and student of the late Max Brödel, has been appointed medical illustrator in the department of visual education.

Million Dollars Offered Texas University.—The Sealy and Smith Foundation of Galveston has offered one million dollars to the University of Texas for a new general hospital unit at Galveston. The gift is contingent on the university's spending about another million dollars for a new hospital, which would furnish some 500 more beds than the 400 now available at John Sealy Hospital. The offer, according to the *Texas State Journal of Medicine*, was made for the construction of a pavilion to be known as the R. Waverley Smith pavilion for both pay and semipay patients. The proposed unit, for which the foundation would also provide x-ray equipment and clinical laboratories, would be joined to the present outpatient clinic and children's hospital. Part of the new construction would occupy the site of the women's dormitory on the medical campus. The regents have agreed to provide a new building for women students. No mention was made of what would become of the old Sealy Hospital building, which, after a tropical storm in 1943, was defined as "safe but not satisfactory." The Sealy and Smith Foundation was established in 1927 to promote the development of the John Sealy Hospital of the University of Texas Medical Branch for the purpose of aiding in the care of the indigent sick of Galveston. Since the foundation was established with bequests of John Sealy Jr. and Mrs. R. Waverley Smith, it has contributed more than \$1,500,000 to the upkeep and support of the hospital and has contributed over \$550,000 toward the expense of new buildings. It continues the benefactions of John Sealy, who died in 1884 and whose will made possible the establishment of the hospital in association with the medical branch in Galveston in 1890.

GENERAL

Gift to Pharmaceutical Foundation.—A total of \$485,000 has been contributed to the American Foundation for Pharmaceutical Education by 300 drug firms, it is reported (*THE JOURNAL*, June 17, p. 506).

Secretary Named for American Bacteriologists.—Leland W. Parr, Ph.D., professor and executive officer of the department of bacteriology, George Washington University School of Medicine, Washington, D. C., is the new secretary-treasurer of the Society of American Bacteriologists. His address is 1335 H Street N.W., Washington 5.

Petition to Form Hospital Libraries Division.—A petition is being circulated to form a hospital libraries division of the American Library Association. If organized, the division would contain parallel sections for hospital, institutional, medical and schools of nursing libraries. Interested persons should communicate with Mrs. Glyde E. Nielsen, secretary-treasurer, Hospital Libraries Round Table, Minneapolis Public Library, Minneapolis.

Officers of Anesthesiology Board.—Dr. Harry Boyd Stewart, Tulsa, Okla., was elected president of the American Board of Anesthesiology, Inc., at its meeting in Chicago, June 9-11. Dr. Philip D. Woodbridge, Philadelphia, was named vice president and Dr. Paul M. Wood, New York, secretary-treasurer. The next written examination of the board will be conducted Jan. 19, 1945 at various medical schools, the first

to be announced later. The next oral examination of the board will be held in New York preceding the annual session of the American Medical Association.

Special Society Elections.—Dr. Harold I. Lillie, Rochester, Minn., was named president of the American Laryngological Association at its annual meeting, June 8. Dr. Arthur W. Proetz, St. Louis, is secretary.—Dr. Samuel W. Hamilton, Washington, D. C., was chosen president-elect of the American Psychiatric Association at its annual meeting in Philadelphia in May and Dr. Karl M. Bowman, San Francisco, was installed as president. Dr. Winfred Overholser, Washington, was reelected secretary-treasurer.

Fund Available for Health Education in Poliomyelitis.—The National Foundation for Infantile Paralysis has set aside \$50,000 for fellowships in health education. Under the program, which has been developed in cooperation with the U. S. Public Health Service, qualified men with certain selective service classifications, as well as qualified women, will begin training this fall. It is believed that trained personnel will be of great assistance in coordinating the community's resources of official and voluntary agencies. Candidates for these fellowships will be chosen by an advisory committee of the U. S. Public Health Service, and those accepted will be assigned to schools of public health at Yale University, University of Michigan and the University of North Carolina. The bachelor of science degree or its equivalent at a recognized college or university is an essential qualification for one of these fellowships leading to the master of science degree in public health. This post-graduate training will consist of nine months' academic work, followed by three months of supervised field experience. Women between the ages of 19 and 40 who have these educational qualifications and who are citizens of the United States are eligible. Men who are United States citizens over 30 years of age also may apply, and the War Manpower Commission has declared Selective Service registrants in 4F and 1A1 classifications as eligible for health education fellowships. A fellowship in health education covers a stipend to the trainee of \$100 monthly for twelve months, tuition and university fees to the school and expenses for field service. Applications are obtainable from the Office of the Surgeon General, U. S. Public Health Service, Washington (14), D. C. Applications must be accompanied by a transcript of college credits and a small photograph and must be in the Office of the Surgeon General not later than August 15.

CANADA

National Department of Health.—If recently proposed actions take place, the department of pensions and national health will cease to exist, according to the *Canadian Journal of Public Health*. This opinion is based on the recent announcement to parliament of the establishment of three departments of government, social welfare, veterans' affairs and reconstruction. According to the *Journal of Public Health* the department of reconstruction will advance and coordinate a broad program designed to meet postwar needs. The department of social welfare will be responsible for the administration of insurance measures and those functions in the field of public health which are under the health branch of the department of pensions and national health. The work of the pensions branch will be assumed by the new department of veterans' affairs. The department of pensions and national health will cease to exist, it was stated. Hospitalization of returned soldiers will be the responsibility of the department of veterans' affairs, causing a separation of hospitalization, which is essentially a health matter, from the department charged largely with the responsibility for health, since the work of the health branch of the department of pensions and national health will presumably be administered by the department of social welfare. The editorial in the *Canadian Journal of Public Health* says it is most disappointing that, if the proposed measures are adopted, Canada will no longer have a national health department, even though the health services may be included in the broad designation "social welfare." The editorial points out that this reorganization raises the whole question of the status of the public health services in the federal government. When the department of national health was established in 1919 there was approval of centralizing public health work in one department which would be represented in the cabinet by the minister of health. In June 1928, when the department of soldiers' civil reestablishment ceased to function, the administration of veterans' affairs was transferred to the department of national health, which subsequently was known as the department of pensions and national health. Today, says the *Journal of Public Health*, sixteen years after the amalgamation of the two departments, the budget for pensions is about fifty times that for national health.

FOREIGN

Activities in Tropical Medicine.—The Swiss Society for Tropical Medicine has been founded at Berne under the presidency of Dr. Paul Thillot, Lausanne, it is reported. It is also announced that an institute for tropical medicine has been founded at Basle.

Australian Named Director of Wellcome Research Laboratories.—Dr. Charles Halliley Kellaway, F.R.S., director of the Walter and Eliza Hall Institute of Research in Pathology and Medicine, Royal Melbourne Hospital, Melbourne, Australia, has been appointed director of the Wellcome Foundation Research Laboratories in England and the United States. Dr. Kellaway will be succeeded in his Melbourne position by Dr. Frank M. Burnet. Dr. Kellaway will be located in London.

Personal.—Dr. James Augustus Wall has been appointed government medical officer at Leeton, New South Wales.—Dr. Gordon Clive Smith has been appointed medical officer for industrial hygiene in the department of public health at New South Wales.—Sir Humpary D. Rolleston has resigned as editor of the *Practitioner*, a position he has held since 1928. Dr. Alan A. Moncrieff, associate editor since 1934, will act as editor.—Sir John Fraser, Bart., regius professor of clinical surgery at the University of Edinburgh, has been appointed to succeed Sir Thomas H. Holland as principal of the University of Edinburgh.

Program for Tuberculosis Control.—Dr. J. Bell Ferguson, state director of tuberculosis control in Victoria, Australia, has launched a tuberculosis control program involving the provision of 2,000 beds at a cost of £606,500. The state government has approved of the provision of 144 beds at an estimated cost of £65,000. The tuberculosis control program includes a radiologic review of every child at the age of 12 years. Legal authority is sought for the detention of sufferers in sanatoriums to prevent transmission. According to a report from the division of medical sciences of the National Research Council, it has been found that between 60 and 70 per cent of all home contacts are infected within five years. It was pointed out that the death rate from tuberculosis in Victoria is increasing. In 1940 it was 42.3 per hundred thousand of population, while in 1942 it was 46.2, with a total of 879 deaths from tuberculosis, the worst record in Australia.

Medical Journals in China.—The *Chinese Medical Journal*, a few copies of which have recently been received in this country, is being published in Chengtu, an unoccupied city of China. Published on cheap paper, the journal is made up under great difficulties. The articles are chosen for their practical value in the free portions of China. They are written in English and hand set, in many cases by Chinese who do not even know the English language. The Medical Abstracts, supplement to the *Chinese Medical Journal*, are being published under similar circumstances. The subscription price per year of the *Journal* and abstracts is 200 national currency. Four issues of the journal published in October 1942 and in January, April and July 1943 contain original articles, editorials, news and correspondence and constitute the series for volume 61A. The October 1942 issue was designated the Chengtu edition, volume one, number one, and contained a preliminary announcement of the sixth biennial conference of the Chinese Medical Association planned for Koloshan, Chungking, May 11-14, 1943. The original articles appear in many cases as contributions of faculty members of the West China Union University, Chengtu, the National Kweiyang Medical College, Kweiyang, the National Central University College of Medicine, Chengtu, the Cheeloo University, Shantung and Chengtu, the United Hospital of the Associated Universities, Chengtu, the National Shanghai Medical College, Chungking, and others. A few illustrations are used. One issue published in 1943 announced that the medical subcommittee of the committee for the promotion of the welfare of the blind had been organized. Mail is sent from the United States to China at a cost of 70 cents a half ounce. This charge applies to mailing rates for medical journals.

CORRECTION

Posterior Dislocation of the Sternal End of the Clavicle.—In the article by Greenlee with this title in *THE JOURNAL*, June 10, page 426, the second sentence in the first paragraph should read "Emphasis has been placed on injuries of the brain in connection with skull fractures, on injuries to the spinal cord in connection with fractures of the spine, on injuries to the lung in connection with rib fractures and on injuries to the bladder, urethra and bowel in connection with fractures of the pelvis."

LONDON

(From Our Regular Correspondent)

June 10, 1944

Postponement of the Annual Representative Meeting of the British Medical Association

The annual representative meeting of the British Medical Association, due to begin July 18 in London, was canceled. So also was the panel conference of the association, which was to have been held in June. The reason for these changes was transportation difficulties, which are greater than ever at this stage of the war and have entailed the cancellation of many meetings of all kinds. The secretary of the British Medical Association wrote to the Ministry of War Transport regarding the holding of the meetings mentioned and received a reply from the minister of health that in view of the difficulties of transportation over long distances it was desirable to avoid the calling of conferences. He regretted that the July conference of the association and also the panel conference should have to be postponed. He expressed hope that it will be possible for these conferences to be held later in the year. He will communicate with the secretary as soon as it is possible to inform him of the removal of present restrictions. Postponement of the representative meeting delays the discussion dealing with the most momentous question that ever occupied the association: the line to be taken with regard to the government's proposal for a national health service. This postponement must greatly delay legislation on the subject.

Ministry of Health Standardizes Tests of Recovery from Venereal Diseases

The Ministry of Health has issued a memorandum for the guidance of medical officers at treatment centers for venereal diseases, specifying the tests which should be employed before discharging persons who have suffered from syphilis or gonorrhea. In the case of gonorrhea it is assumed that treatment has been continued until evidence of persisting infection has disappeared. The blood should be examined a week after treatment has been suspended and every month thereafter for a minimum of three months for the serum reactions. Men should be provided with microscopic slides and instructed how to spread them when any urethral discharge may appear. A week after suspending treatment the early morning urine, or urine held for a minimum of four hours, should be examined for heavy threads after an attempt to obtain discharge at the meatus. Any threads or discharge should be examined bacteriologically. Specimens of prostatic and vesicular secretion should be obtained for microscopic examination. Cultures of both urethral and prostatovesical secretion are desirable. If no evidence of persisting infection is obtained, an attempt should be made to stimulate discharge by filling the anterior urethra with a provocative solution, such as a 1 in 6 dilution of iodine 1, potassium iodide 2 and distilled water 300 parts. This should be retained for over two minutes. As a further provocative measure the prostate and seminal vesicles should be massaged after the bladder has been emptied, and the secretion should be left in the urethra. If no evidence of relapse is obtained, these measures should be repeated weekly for one month and thereafter each month for two or more months. At the end of this time the anterior urethra should be examined with a urethroscope, and a full sized metal sound passed into the bladder. These manipulations may produce a discharge, of which the patient should be warned to obtain a specimen.

In the case of women a week after suspending treatment specimens should be taken from the urethra, cervical canal and rectum and examined in stained smear and culture. In the case of the urethra and cervical canal, specimens should preferably

be taken the day after painting with a provocative chemical such as that described. In addition the examination should include inspection of the orifices of the Bartholinian and any paraurethral ducts, with bacteriologic examination of any secretion which can be expressed. This process should be repeated weekly for a month and thereafter every month for three months, the specimens being taken just after menstruation if this is occurring. Before final discharge, careful pelvic examination should exclude any residue of infection in the pelvic viscera.

In cases of syphilis the blood should be tested every three months after completing treatment for the first year and every six months for the second year. The spinal fluid should be tested at the end of treatment or earlier if the blood reactions are resistant, and the test should be repeated at the end of two years of observation. These tests are regarded as minimal for both sexes. If any relapse has occurred, both blood and spinal fluid should be tested more frequently. In the case of women satisfaction of these tests is not considered a sufficient safeguard against infection of the fetus in case of pregnancy, and treatment throughout the whole period of gestation is advised.

Care of the Student's Health

A pamphlet entitled "Health and the Student" has been produced by the collaboration of four students organizations—the National Union of Students, the British Medical Students' Association, the British Dental Students' Association and the Scottish National Union of Students. It describes an elaborate scheme for the care of students. All students should be medically examined on entry to the university and subsequently at regular intervals by a full time university medical officer who would also give lectures; the pamphlet recommends X-ray examination of the chest should be performed on admission and at six month intervals. There should be a biennial Mantoux test. Regular dental inspection is desirable. In regard to mental health the dangers of a narrow scholastic outlook are emphasized. University authorities should give attention to the supply of cheap lodgings or hostels and good food, the authors believe.

Good use should be made of existing playfields, and where they are scarce they should be shared with other groups of young people, such as youth and sports clubs, irrespective of ownership. If the shortage of doctors at present makes regular medical inspection of all students impossible, it should be arranged at least for medical and dental students, who are more exposed to infection than others. The cost of protecting the students' health could be covered by a comprehensive insurance scheme, it is stated. So far, only one full time university medical officer has been appointed—at Birmingham.

E Hurry Fenwick

The death at the age of 88 of Mr. E. Hurry Fenwick removes a man who in the first quarter of the century was the most prominent urologist in this country. The son of Samuel Fenwick, physician to the London Hospital, he was educated there, qualifying in 1880. After postgraduate study on the continent, particularly at Berlin and Leipzig, he became assistant surgeon to the London Hospital and later to St. Peter's Hospital for Genito-Urinary Diseases. He was one of the first to use Nitze's cystoscope. An excellent teacher and prolific writer, he had ten books to his credit, which were largely based on his extensive experience. When the International Congress of Medicine met in London in 1913 he was president of the section of urology. Fenwick was quick to apply Roentgen's discovery and in 1905 designed the first ureteral bougie opaque to the rays. He played a large part in the advances in the visual examination of the bladder. He kept full records of his cases on which he based his practical teaching. Recently, at 87, he contributed to the *British Medical Journal* a note on the "Expectation of Life After Nephrectomy for Urinary Tuberculosis."

BOLIVIA

(From Our Regular Correspondent)

April 18, 1944.

Incidence of Right and Left Eye Trauma
in Industry

The relative incidence of injury to the right and left eye has been investigated on some 58,000 miners whose records are available to the Bolivian Health Security Board. The total number of accidents listed was 8,396. Among these were 579 accidents involving one or both eyes: 229, or 39.5 per cent, involved the right eye; 282, or 48.7 per cent, the left eye, and 68, or 11.7 per cent, both eyes. In three different mining companies there were accurate histories of 257 cases of eye injury. Of these, 92, or 35.8 per cent, involved the right eye, 133, or 51.7 per cent, the left eye and 32, or 12.4 per cent, involved both eyes. "Mining" as used here refers to accidents peculiar to mining work, such as breaking rock by machine or by hand. "Stone breaking" refers exclusively to the breaking of larger stones with a hammer, inside or outside the mines. "Different occupations" includes all the other types of work, performed mostly by unskilled workmen; blows, carelessness by associates and similar accidents occurring during work hours, but not directly as a result of work. There were no available figures as to the number of engines employed in each company.

TABLE 1.—Frequency of Right and Left Eye Involvement on Various Jobs

Side	Mining		Mechanic		Carpenter		Arc Welder		Stone Breaker		Caustics		Different Workers	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Right eye	16	6.23	29	11.28	6	2.33	8	3.10	33	12.84
Left eye	24	9.34	39	15.17	4	1.56	15	5.84	9	3.50	42	16.34
Both eyes	9	3.50	5	1.95	10	3.89	5	1.95	3	1.17

Relatively frequent are eye accidents among engineers, although there was only an average of 4.5 per cent of this profession employed in the entire staff.

The more frequent involvement of the left eye on different jobs is shown in table 1. The difference between right and left eye accidents in the miner's job is striking (24 of the left eye as against 16 of the right) and among engineers (39 of the left as against 29 for the right).

CAUSES FOR DIFFERENCE IN FREQUENCY OF INVOLVEMENT
OF THE RIGHT AND THE LEFT EYE

Miners.—The miner's specific work consists of drilling holes in the rock. This work is done with a perforator engine, mostly without water protection; or by hand, using chisel and hammer to make a hole which will later be loaded with dynamite. When working with the perforator, most workmen hold it alternately on each shoulder, so that there is an equal chance to get a foreign body into either eye. When drilling holes by hand, the man holds his hammer in his right hand, the chisel in his left. Swinging the hammer, he holds the chisel in his left hand, turning it around its longitudinal axis. Most of these eye accidents seem to happen during the first blows. The man is constantly bending his left side forward, his right eye being partially protected against splinters by his nose. The higher incidence of left eye accidents in this particular job may be attributed to this factor.

Engineers.—There is a higher incidence of eye accidents in this job than in any other, 28.40 per cent in the present study. In all the companies investigated, the number of engineers employed does not exceed an average of 4.5 per cent of all workmen employed. Most of the accidents are caused by carelessness. The mechanics are ordered to use protective glasses when working with certain tools such as chisels or grindstone. As to the distribution of accidents among engineers, the figures in table 2 indicate the tools used.

Noteworthy is the relatively higher incidence of accidents caused by working with the chisel.

Arc Welders.—A bad habit exists among these workers: when beginning a new welding wire they clean the isolated tip after placing the electrode in the handle by rubbing against the connecting iron pieces, causing many small arcs, without dropping the protective shield. As this rubbing is mostly effected from the left to the right side of the body, there is

TABLE 2.—Frequency of Right and Left Eye Involvement
Among Mechanics as to the Tools Used

Tool	Right Eye		Left Eye		Both Eyes	
	No.	%	No.	%	No.	%
Chisel	6	8.22	17	23.30
Turning lathe	2	2.74	3	4.11
Grind stone	21	28.77	19	26.03
Hot air, fumes	5	6.85

obviously more chance to get the arc flash burn in the left eye, but there is no other evidence that this is the only cause for higher left eye involvement. All the cases referred to as "arc welding" were diagnosed as flash conjunctivitis.

Other Occupations.—A somewhat higher incidence of left eye involvement was found only in one other type of work: intro-

duction into the eye of foreign bodies while sweeping the workroom floor with a broom. In this series there were 32 cases thus distributed: right eye 8 cases, left eye 23 cases, both eyes 1 case.

As to the seriousness of these 579 eye accidents, there was only one perforation of the right eye; all other accidents amounted only to introduction or incrustation of foreign bodies, irritative conjunctivitis produced by arc welding, hot air, fumes, caustics and the introduction of the relatively acid water.

CONCLUSIONS

In a series of 8,396 accidents, there were 579 eye accidents, or 6.89 per cent. Accurate investigation of 257 cases disclosed left eye involvement to be as high as 51.75 per cent as against 35.80 per cent for the right eye. Most exposed to eye accidents were engineers (28.40 per cent), although there was only an average of 4.5 per cent of engineers in the whole staff. Next in order were miners. Most left eye accidents occurred while working with a chisel. A little higher incidence of left eye accidents was noted also among unskilled workers sweeping floors, and among arc welders. The present study is a fair cross section of a large number of all types of accidents recorded by several mining companies.

Marriages

FURNIFOLD McLENDEL SIMMONS PATTERSON, New Bern, N. C., to Miss Ruth Adriel Read of Philadelphia, June 13.

JEREMIAH HENRY HOLLEMAN, Pickens, Miss., to Miss Agnes Willette Smith of Greenwood, June 12.

VANCE BENTON ROLLINS, Henderson, N. C., to Miss Carrie Lee Laney of Camden, Ark., June 20.

JAMES ROBERT FLAUTT JR., Swan Lake, Miss., to Miss Mary Louise Smith in Clarksdale, June 20.

Deaths

William Thornwall Davis * Washington, D. C.; *Columbia University Medical Department, Washington, 1901*; since 1920 professor of ophthalmology at the *George Washington University School of Medicine*; professor of ophthalmology at the *U. S. Army Medical School, 1917-1918*; a first lieutenant and later a captain in the medical corps of the *U. S. Army* from 1902 to 1913; served under *Gen. Leonard Wood* in the Philippines in the Moro campaign of 1904-1905 and under *Gen. Frank McCoy* in the *Datu Ali Campaign* in 1905; a major in the medical corps of the *U. S. Army* during *World War I*; served as a member of the advisory board, *Selective Service Board*; specialist certified by the *American Board of Ophthalmology*; member and in 1935 first vice president of the *American Academy of Ophthalmology and Otolaryngology*; member and at one time member of the council and chairman of the executive committee council of the *Southern Medical Association*; member of the *Pan American Medical Association* and the *Washington Academy of Medicine*; a member of the *Sons of the American Revolution, Military Order of Foreign Wars of the United States, Military Order of the Caraboa, Spanish-American War veterans* and others; in 1940 was decorated with the *Order of Carlos J. Finlay*; consultant and chief of service in ophthalmology, *George Washington University Hospital*; senior surgeon at the *Episcopal Eye, Ear and Throat Hospital*; consulting ophthalmologist, *Garfield, Columbia, Gallinger and Casualty hospitals*; member of the board of directors of the *Washington Loan and Trust Company*; died June 15, aged 67.

Joseph Brennemann * Reading, Vt.; *Northwestern University Medical School, Chicago, 1900*; professor of pediatrics at the *University of Chicago School of Medicine* from 1921 to 1941; chief of staff of the *Children's Memorial Hospital, Chicago*, from 1921 to Jan. 1, 1941, when he resigned after serving three years beyond the retirement age; at one time attending pediatrician at the *Cook County, St. Luke's and Wesley Memorial hospitals* in Chicago; professor of pediatrics at the *University of Southern California School of Medicine, Los Angeles*, from 1941 to 1943; served as chief of staff at the *Children's Hospital in Los Angeles*; specialist certified by the *American Board of Pediatrics, Inc.*; an *Affiliate Fellow* of the *American Medical Association*; member of the *Illinois State Medical Society, American Academy of Pediatrics, Central States Pediatric Society and the Institute of Medicine of Chicago*; honorary member of the *British Pediatric Society*; member and past president of the *American Pediatric Society* and the *Chicago Pediatric Society*; editor of "*Brennemann's Practice of Pediatrics*"; died July 2, aged 71.

Carl Fisher * Los Angeles; *Harvard Medical School, Boston, 1905*; clinical professor of surgery (ophthalmology) at the *University of Southern California School of Medicine*; entered the *Mayo Clinic, Rochester, Minn.*, as head of the section on ophthalmology and otology on May 1, 1909 and resigned July 1, 1917; major in the medical corps, *American Expeditionary Forces*, serving at *Base Hospitals number 26, 115 and 57* during *World War I*; specialist certified by the *American Board of Ophthalmology*; member of the *American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, Association for Research in Ophthalmology, Inc., Western Ophthalmological Society, Pacific Coast Ophthalmological Society, Los Angeles Ophthalmological Society and the Alumni Association of the Mayo Foundation*; a member of the staffs of the *Good Hope Clinic, the Eye and Ear Hospital, St. Vincent's Hospital and the Hospital of the Good Samaritan*; died June 7, aged 64.

Paul Judd Sartain * Philadelphia; *University of Pennsylvania Department of Medicine, Philadelphia, 1886*; specialist certified by the *American Board of Ophthalmology*; member of the *American Academy of Ophthalmology and Otolaryngology*; fellow of the *College of Physicians of Philadelphia*; member of the *Franklin Institute, Historical Society of Pennsylvania, Zoological Society of Philadelphia, Oxford Ophthalmological Congress, Colonial Society of Pennsylvania and the Société Française d'Ophthalmologie*; since 1894 secretary of the *Geographical Society of Philadelphia*; a member of the *Medical Club of Philadelphia*, of which he was vice president in 1925; died April 9, aged 82.

Alonzo Cass Tenney, Chicago; the *Hahnemann Medical College and Hospital, Chicago, 1895*; member of the *Illinois State Medical Society*; formerly adjunct professor of pathology and the theory and practice of medicine at his alma mater; professor of physical diagnosis at the *Illinois Post-Graduate Medical School* from 1916 to 1919; medical examiner for the

Illinois Civil Service Commission from 1915 to 1919; member of the consulting staff of the *Illinois Masonic Hospital*; on the courtesy staff of the *Henrotin Hospital*; died in the *Research and Educational Hospital, University of Illinois, May 8, aged 70*, of coronary insufficiency, decompensation and diabetes mellitus.

Francis Milton Shookley * Stamford, Conn.; *University Medical College of Kansas City, Mo., 1913*; specialist certified by the *American Board of Psychiatry and Neurology, Inc.*; served in the medical corps of the *U. S. Army* during *World War I*; lieutenant colonel in the medical reserve corps of the *U. S. Army* not on active duty; in 1942 was chosen vice president of the *Connecticut Society for Psychiatry and Neurology*; formerly physician in charge of *Stamford Hall*; consultant in psychiatry at the *Stamford Hospital*; died in the *Veterans Administration Facility, New York, April 25, aged 54*, of hypertension and coronary heart disease.

Allison Temple Wanamaker * Seattle; *Northwestern University Medical School, Chicago, 1907*; specialist certified by the *American Board of Otolaryngology*; past president of the *King County Medical Society*; member of the *American Laryngological Association, American Laryngological, Rhinological and Otolological Society and the Pacific Coast Otolaryngological Society*; fellow of the *American College of Surgeons*; member of the executive committee and staff, *King County Hospital*; on the staffs of the *Children's Orthopedic, Providence and the Swedish hospitals*; died June 21, aged 63.

Gordon Ira Trevett, Baltimore; *Cornell University Medical College, New York, 1936*; instructor in preventive medicine at the *Johns Hopkins University School of Medicine*; served as instructor in preventive medicine at the *Johns Hopkins University School of Hygiene and Public Health*; formerly an intern in surgery at the *New York Hospital and intern in medicine* at the *Strong Memorial and Rochester Municipal hospitals, Rochester, N. Y.*, where he had been a resident in internal medicine; since Sept. 1, 1940 assistant dispensary physician at the *Johns Hopkins Hospital*, where he died May 3, aged 32, of carcinoma of the rectum with metastases.

Ida E. Shope Bishop, Winslow, Ariz.; *Woman's Medical College of Georgia and Training School for Nurses, Atlanta, 1892*; died April 29, aged 88, of senility.

Frank T. Carmer, Newfane, N. Y.; *University of Buffalo School of Medicine, 1894*; member of the *Medical Society of the State of New York*; served as acting assistant surgeon in the *U. S. Public Health Service*; health officer of *Lockport*, and county coroner; on the staff of the *Lockport City Hospital, Lockport*; died April 16, aged 75, of cerebral hemorrhage.

Herbert Ross Clark, Pierce City, Mo.; *Beaumont Hospital Medical College, St. Louis, 1901*; served during *World War I*; died April 9, aged 67, of chronic myocarditis and terminal nephritis.

James A. Garfield Clayton, Eaton, Colo.; *Hering Medical College, Chicago, 1905*; member of the *Colorado State Medical Society*; at one time mayor of *Craig*, member of the city council and coroner of *Moffat County*; on the staff of the *Greeley Hospital, Greeley*, where he died April 12, aged 62, of duodenal ulcer hemorrhage.

Carroll Stoll Davenport * Lansing, Mich.; *University of Michigan Medical School, Ann Arbor, 1922*; specialist certified by the *American Board of Radiology, Inc.*; formerly instructor in roentgenology at his alma mater; member of the *Detroit Roentgen-Ray and Radiological Society and the Michigan Association of Radiologists*; in charge of the x-ray department of *St. Lawrence Hospital*, where he died April 26, aged 46, of coronary spasm.

Walter Martin Droll, Alta Vista, Kan.; *Rush Medical College, Chicago, 1893*; served as coroner of *Wabaunsee County*; on the staff of the *Newman Memorial County Hospital, Emporia*; died March 28, aged 75.

Willoughby George Dye * Los Angeles; *Northwestern University Medical School, Chicago, 1901*; fellow of the *American College of Surgeons*; served during *World War I*; at one time on the staff of *St. Joseph's Hospital, Deer Lodge, Mont.*; died in *St. John's Hospital* April 1, aged 70, of congestive heart disease.

John Clement Ellis * Panama City, Fla.; *Atlanta College of Physicians and Surgeons, 1906*; served during *World War I*; company physician for the *Wainwright Shipbuilding Company*; instrumental in organizing the *Taylor County Health Unit*; past president and secretary of the *Taylor County Medical Society*; died April 19, aged 61, of coronary occlusion.

Paul Smith Fox, Athens, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; served as president of the village and member of the board of education; died in the Community Hospital, Battle Creek, April 26, aged 83, of pneumonia.

Norman Wilkinson Gillespie, Boston; Harvard Medical School, Boston, 1915; member of the Massachusetts Medical Society; a first lieutenant in the medical corps of the U. S. Army during World War I; on the staff of the Boston Lying-in Hospital; died April 28, aged 56, of acute coronary occlusion.

Henry Harrison Harvey, La Mesa, Calif.; University of Denver Medical Department, 1897; died April 3, aged 67, of coronary sclerosis.

Fred Hexamer, Newark, N. J.; University of the City of New York Medical Department, New York, 1888; member of the Medical Society of New Jersey; died April 28, aged 77, of cerebral hemorrhage.

Charles Tilden Hunt, Dayton, Ohio, Miami Medical College, Cincinnati, 1906; member of the Ohio State Medical Association; served in the medical corps of the U. S. Army during World War I; died in Detroit April 28, aged 67, of coronary thrombosis.

Paul Mallers Hunter * San Marino, Calif.; Chicago College of Medicine and Surgery, 1917; served during World War I; formerly affiliated with the Collis P. and Howard Huntington Memorial Hospital, Pasadena; died in Pasadena April 29, aged 53, of coronary thrombosis.

Robert Everett Jones, Denver; Marquette University School of Medicine, Milwaukee, 1935; member of the Colorado State Medical Society; served an internship at St. Luke's Hospital and a residency at the Children's Hospital; died April 12, aged 36, of pulmonary embolism.

Robert Maxwell I. Kinnear, La Crosse, Wis.; Chicago Homeopathic Medical College, 1890; died in a local hospital April 15, aged 83, of carcinoma of sigmoid and colon and arteriosclerosis.

Theodore Kroesch * Enterprise, Kan.; Rush Medical College, Chicago, 1905; county health officer; found dead April 5, aged 63, of poison, self administered.

Charles Lewis, St. Louis; St. Louis College of Physicians and Surgeons, 1891; died in the De Paul Hospital April 18, aged 82, of heart disease and a fractured hip received in a fall.

Bernard Graves Marr, Dyersburg, Tenn.; University of Louisville (Ky.) Medical Department, 1911, member of the Tennessee State Medical Association; served on the staff of the Baird Brewster Hospital; died April 23, aged 60, of pernicious anemia.

Thaddeus Leander Mathers, Matherville, Miss.; Medical College of Alabama, Mobile, 1904; died April 18, aged 87, of coronary thrombosis.

James Francis McCaw, Watertown, N. Y.; College of Physicians and Surgeons, New York, 1892; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otolological Society and formerly vice president; member of the American Otolological Society, Inc.; fellow of the American College of Surgeons; served on the staffs of the Jefferson County Orphan Asylum and the House of the Good Samaritan, where he died April 29, aged 80, of coronary thrombosis.

Charles Henry McHaffie, Ash Grove, Mo.; Ensworth Medical College, St. Joseph, 1906; member of the Missouri State Medical Association; veteran of the Spanish-American War; served overseas as a captain in the medical corps of the U. S. Army during World War I; died in the Springfield

Baptist Hospital, Springfield, April 12, aged 64, of pulmonary embolism following an operation.

Charles D. Mohler, Hastings, Mich.; Detroit College of Medicine, 1905; served as health officer; on the staff of the Penneck Hospital; died April 27, aged 65, of heart disease.

Grant B. Nichols, Wapakoneta, Ohio; Medical College of Ohio, Cincinnati, 1883; member of the board of education; surgeon for the Western Ohio Railroad; died April 26, aged 82, of cerebral embolism.

George Gibson Parlow, Wareham, Mass.; College of Physicians and Surgeons, Boston, 1905; member of the Massachusetts Medical Society; a captain in the medical corps of the U. S. Army during World War I; formerly a member of the board of health and the school board; at one time on the staffs of the Fall River General and Union hospitals, Fall River; died April 20, aged 74, of cerebral thrombosis and arteriosclerosis.

George Burgess Pierce, New York; Harvard Medical School, Boston, 1898; died in the New York Hospital May 3, aged 68, of hypertensive cardiovascular disease with arteriosclerotic heart disease.

Edward Reinert * Columbus, Ohio; Ohio Medical University, Columbus, 1897; member of the American Radium Society; at one time night physician for the Ohio State Peni-

tentiary, surgeon to the city police department and assistant superintendent of the city board of health; formerly a member of the state board of administration; died in the Grant Hospital April 30, aged 70, of aplastic anemia due to radium and x-ray emanation.

James Blaine Shoemaker * Miami, Ind.; Pulte Medical College, Homeopathic, Cincinnati, 1910; served during World War I; died in Crow Wing Township, Minn., May 13, aged 59, of coronary thrombosis.

Aloysius Joseph Wochinski, Chicago; Loyola University School of Medicine, Chicago, 1918; member of the Illinois State Medical Society

and the American Urological Association; fellow of the American College of Surgeons; specialist certified by the American Board of Urology, Inc.; associate clinical professor of urology at his alma mater; attending genitourinary surgeon, Alexian Brothers' and Columbus hospitals; died May 30, aged 51, of coronary occlusion.

KILLED IN ACTION

Richard Monroe Forsythe, East Cleveland, Ohio; Western Reserve University School of Medicine, Cleveland, 1937; served a residency at the Grasslands Hospital in Valhalla, N. Y., and the Le Roy Sanitarium in New York; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on May 31, 1940; later promoted to lieutenant and lieutenant commander; died of wounds received in action in the Southwest Pacific area March 30, aged 30.

Carl Oscar Nord, Drexel, Mo.; Northwestern University Medical School, Chicago, 1943; served an internship at St. Luke's Hospital in Kansas City, Mo.; commissioned a first lieutenant in the medical corps, Army of the United States, on June 12, 1943 and began active duty at Carlisle Barracks, Pa., on July 13, 1943; later promoted to captain; served with the 45th infantry division on the Anzio beachhead; killed in action in the North African theater May 15, aged 32.

LIEUT. COMDR. RICHARD M. FORSYTHE
(M.C.), U.S.N.R., 1913-1944

CAPT. CARL O. NORD, M. C.,
A. U. S., 1912-1944

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 increased the Food and Drug Administration's control of the advertising claims and statements made on the label of a medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1943 follow in this form: name of product, name of distributor, date of issuance of complaint, date of issuance of Cease and Desist Order and terms of order.

Amogen Tablets.—J. R. Hodges, trading as Amogen Company, San Antonio, Texas, complaint issued Sept. 21, 1942; order issued July 31, 1943. Order directed Hodges to discontinue any advertisements which misrepresented the properties of these tablets and failed to reveal the harmful results from long continued use of them. The order further directed Hodges to cease representing that his product is a cure or remedy for, or has any value in the treatment of, malaria, common colds and fevers, poor digestion, acid or gas on the stomach, neuralgia, rheumatic pains and fever, sallow complexion, boils, skin irritations or over-indulgence in food and drink, that it offers any benefit in biliousness, excess bile in the system, headaches, coated tongue, or bad taste in the mouth, in excess of temporary laxative relief, as when such conditions are due to constipation, or that it will rid the system of poisons or enable the user to avoid sickness or maintain good health. The order further directed the respondent to discontinue any advertisement which did not reveal that continued use of Amogen Tablets over a long period of time may result in mercury poisoning, and that the product should not be used in case of abdominal pains, nausea or other symptoms of appendicitis, provided, however, that such advertisement need contain only the statement, "Caution: Use only as directed" if the directions for use, when appearing on the label, contain warnings to the same effect. The Commission found that the preparation is essentially a laxative containing calomel, a mercury derivative, that its continued use may result in mercury poisoning and serious injury to health, and that it has no value in the treatment of the disorders for which it has been advertised. The Journal for August 29, 1942, page 1522, recorded a stipulation which J. R. Hodges entered into with the Commission in July 1941, in which he had agreed to discontinue some of the foregoing objectionable misrepresentations.

Domestic Short-Wave Diathermy.—Max E. Heyman and Maude S. Jaret, trading as Domestic Diathermy Company, New York, complaint issued April 16, 1943; order issued June 21, 1943. Order directed these respondents to discontinue the following advertising misrepresentations: That their device is safe or harmless or that, when used by unskilled laymen in the treatment of self-diagnosed conditions, it constitutes a competent treatment of, or remedy for, rheumatism, arthritis, sciatica, neuralgia, lumbago, sinus trouble, neuritis, laryngitis, tonsillitis, bursters, asthma, female complaints, and some other things, that its use will renew youthful vigor and establish bodily efficiency and resistance to disease, and that the treatment which the device provides is similar to that known as "friendly fever." The order further prohibited dissemination of any advertising which would fail to reveal clearly and conspicuously that this mechanism is not safe to use for any condition unless a competent medical authority has determined by diagnosis that diathermy is indicated and has prescribed the frequency and rate of application of the treatments and the user has been adequately instructed by a trained technician in the use of the device.

Dorothy Gray Cosmetics.—Lehn & Fink Products Corporation, and its subsidiary, Dorothy Gray, Ltd., both at Bloomfield, N. J., complaint issued June 4, 1938, order issued June 24, 1943. Order directed the respondents

to cease representing that the vitamin D content in their cosmetic creams will cause the coloring of the skin to be cleared or brightened, make skin texture softer, smooth lines, or provide any beneficial effect whatever, or that treatment with these preparations tightens the relaxed contour of the face, stimulates lagging circulation or clears the pores of dirt. The order, however, permitted the respondents to represent that such creams may remove superficial accumulations of dirt from the pore openings. The order further directed the respondents to cease representing that their "Special Tanning Oil," when used alone or in combination with their other products, will penetrate the skin, or that their preparations, on the whole, will remove, counteract or fortify against lines or wrinkles in the skin. It did not, however, prohibit the representation that an emollient cream which lubricates the skin will aid in smoothing out lines caused solely by dryness of the skin.

Elsaco Mineralized Water.—Electrovita Sales Company of Ohio, Norwalk, Ohio, complaint issued Oct. 26, 1942, order issued August 6, 1943. Order directed respondent to cease representing that the product has any beneficial effect other than a tendency to decrease stomach acidity, that it will neutralize any acid condition of the blood stream or rid the body of an acid condition, that it has any beneficial effect in activating the kidneys, that it will supply mineral deficiencies or essential mineral salts needed to keep the body chemistry in balance, or act as an oxidizing agent, that it has any value in treating asthma, kidney or bladder trouble, or any of the numerous diseases named in the advertising, or any other human ailment. The Commission found that the product was essentially the same as ordinary tap water, except for an added amount of calcium hydroxide which could not be obtained by any electrolytic method, but simply was physically added in the course of processing the water.

Fernet-Branca.—Fratelli Branca & Company, Inc., New York, complaint issued Sept. 5, 1942, order issued June 11, 1943. Order directed the respondent to cease representing that the preparation is a cure or remedy for stomach disorders, indigestion, headache, insomnia or liver ailments, or would have any value in the treatment of menstrual disturbances. The record shows that in March 1938 the concern had stipulated with the Commission that it would discontinue certain advertising representations similar to those mentioned above.

Kelp-A-Malt Tablets.—Associated Laboratories, Inc., Long Island City, N. Y., also known as Allied Laboratories, Kelp-A-Malt Company and Seedol Company, complaint issued Nov. 20, 1936; order issued July 26, 1943. Order directed respondents to cease representing that these tablets will enable those who are weak, emaciated, thin or underweight to overcome such conditions, or persons who are tired or run down to regain health, strength or vigor, that a well proportioned body can be acquired through use of the product, or that these tablets possess any value in the treatment of sour or acid stomach, gas or indigestion. Among the findings of the Commission in this case were that Kelp-A-Malt Tablets contain vitamin B₁, iron, iodine, calcium and phosphorus.

Lakota.—Bertha M. Urban, Living, Neb., complaint issued May 21, 1942, order issued July 24, 1943. Order directed the respondent to discontinue the following misrepresentations in her advertisements of Lakota, a fruit juice: That the product has any medicinal value in the treatment of migraine or sick headache, high blood pressure or abdominal pains or ulcers, that the use of it will remove the cause of migraine headache or relieve the pain or discomfort associated with such condition, or that it has any value in treating constipation. The Commission's findings were that Lakota is composed entirely of the liquid obtained from boiling dried prunes, with ordinary brown or white sugar, and water.

Latta Cream.—M. L. Kay and Humbert O'Camp, trading as Latta Cream New York, complaint issued March 6, 1943, order issued June 19, 1943. Order directed respondents to discontinue any advertisement which represented that this cosmetic will give a youthful and beautiful appearance and make one look younger, that it will effectively remove and eradicate wrinkles, lines, baggy eyes, double chin, sagging muscles or other signs of age, or that the youthful appearance of motion picture stars is brought about through the use of this preparation.

Mercorized Wax.—Dearborn Supply Company, Chicago, complaint issued Sept. 25, 1938. The first order was issued August 20, 1939, and, among other things, directed the company to discontinue advertisements which did not reveal that Mercorized Wax contains ammoniated mercury or that its use may injure some persons under certain conditions. The supplemental order issued July 17, 1943, called attention to the first one, and brought out the fact that the use of products containing ammoniated mercury in excessive amounts and in frequent applications is likely to result in erythema, edema, inflammation, irritation or other manifestations of dermatitis, particularly if the skin was cut or broken before the application. The order directed the concern in question to discontinue any advertisements which did not reveal that Mercorized Wax should not be applied to an area of the skin larger than the face and neck at any one time, that too frequent application over excessive periods of time should be avoided, that adequate rest periods between series of treatments should be observed, that the preparation should not be applied where the skin is cut or broken, and that in all cases a proper patch test should be made to determine whether the patient is allergic or sensitive to the product. The stipulation provided, however, that the statement, "Caution: Use only as directed" would be a sufficient warning in the advertising, provided that the same statement should appear on the labels.

Correspondence

SEEING EYE DOGS FOR BLINDED VETERANS

To the Editor—Your Current Comment in the June 3 issue of *THE JOURNAL*, dealing with the act to furnish seeing eye or guide dogs and other necessary equipment deemed useful in their rehabilitation to blinded soldiers, contains several misstatements.

The American Association of Workers for the Blind, the largest professional affiliation of workers for the blind in North America, did not take the view that this was unnecessary legislation and that its purposes could have been achieved satisfactorily through private agencies for the blind. Rather did it, through its Legislative Committee endorse H. R. 4519 and urge its passage. So also did the Joint Legislative Committee of the American Association of Workers for the Blind and the American Association of Instructors for the Blind (of which I am secretary).

Whether there is one blinded veteran or whether there may be several hundred, we view the matter as one of federal responsibility, supplementing other provisions (including those in Public Law 16 of the 78th Congress) for a comprehensive program of vocational rehabilitation for blinded soldiers. Having given their sight in the service of their country, blinded veterans should not be left to depend on the caprice or ability of the private agency to offer them such services and in such individually selected cases as these private agencies may desire or be able to accommodate. Rather does the American people, through its government, owe it to these veterans to assure that nothing is left undone to secure their rehabilitation, as a matter of right through law, not because of public largesse in response to agency begging in their behalf.

Prior to the enactment of this legislation there developed in various parts of the United States many sporadic movements claimed by their sponsors to be for the purpose of furnishing guide dogs to blinded veterans. In connection with these movements many false and fraudulent representations were made both as to the overall number of blinded service personnel and as to individual cases. The public has been victimized by some of these appeals and generally speaking there has been an "open season" on blinded soldier appeals which has had the effect of degrading the veterans and of fostering the idea that their government has neglected them and that consequently private agencies have felt compelled to beg in their behalf. This legislation will now protect both the blinded veterans and the public against such appeals. Self interest was largely in evidence on the part of those opposing it.

As enacted the legislation simply places a ceiling of \$1,000,000 on the amount which may be spent for the purposes outlined. It does not require the expenditure of this amount and unless needed the sum may not all be spent. But whether there are few or many blind veterans it should be remembered that dogs can serve only for limited periods and that replacements will be necessary and can be provided through this measure. Incidentally, in the opinion of many, considerably more than 10 per cent of the blinded veterans will be found able and eager to use a dog. The factors involved differ materially from the civilian problem.

What is the alternative? In most cases guide-dog schools serving the civilian blind have expressed a willingness to give

priority to the blind veteran, but some still require payment by the veteran of the sum charged to civilian blind, usually \$150, representing only a small part of the cost the rest of which is provided through public contributions to these private agencies. We can find no reason why blinded veterans should be expected to pay \$150 for a dog and a similar sum every seven or eight years for a replacement or for the private agency to be continually obliged to beg for funds to make up additional costs connected with the furnishing of dogs—which appeals, like the brook, might go on for ever.

The blind veteran is entitled to every necessary service which a grateful country can by law make available to him and those who oppose such legislation would do well to ask themselves whether they prefer that we indulge in private begging as the alternative to federal responsibility.

Your statement that the total blinded in the first world war had been well under 500 for both Great Britain and the United States is quite inaccurate. My good friend Lieut. Col. Sir Ian Fraser, chairman of St. Dunstan's, has many times stated that nearly 800 British and Empire service personnel were blinded in the period 1914-1918, and that there were approximately 2,200 more postwar cases of service connected blindness. And more than a year ago he reported 310 cases of service and civilian blinded in Britain in the present war, a figure in excess of Brigadier General Hillman's and one now already considerably surpassed.

ALFRED ALLEN, Winnethka, Ill.

Secretary General, American Association
of Workers for the Blind

[NOTE—The letter was referred to the Office of the Surgeon General, which submits the following comment.]

To the Editor—The comments of Mr. Alfred Allen of the American Association of Workers for the Blind are carefully considered and most convincing. All are agreed that service personnel who lose their eyesight in the service of their country must have the very finest medical and surgical care and the very best opportunity for complete rehabilitation. We would believe, as was stated so ably in General Hillman's article, that the decision to employ guide dogs should not be made until the man has received a good bit of training himself. Whether it is proper for the soldier to receive a guide dog through a reputable private agency or whether it is better that the dog and the training be supplied by the federal government is a matter of opinion. Such opinions, moreover, are often related to political philosophy. Several guide dog agencies have agreed to provide a fully trained dog and the training for the man at no cost or at a nominal fee. It is true that only one of the guide dog agencies has in its agreement the provision of replacement of the dog without additional cost. It is believed further, that the pension paid for blindness acquired as a result of military service is adequate to meet the usual expenses, it would not be fair to speak of "begging" in view of this fact.

As to the statistics of blindness in World War I, General Hillman's paper in the June 3 issue of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* reads as follows: "As a result of World War I France in 1922 had 2,200 blinded pensioners. Great Britain had slightly under 3,000." The present figures for blindness in Great Britain are not known. Some months ago the unofficial figure of 288 was reported to this office through a reliable source. We regret that we have no means at hand to give you accurate data for Great Britain's present problem.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, July 8, page 748.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Aug. 7-9 and Nov. 13-15. Part III. Various centers, September or October. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Part I. Various centers, Jan. 19. Final date for filing application is Oct. 21. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Various centers, Oct. 16. Candidates in military service may take examination at their place of duty. Final date for filing application is August 15. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I. Various centers, February. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 5-7. Los Angeles, January. Final date for filing application is Oct. 1. Sec., Dr. S. Judd Beach, 56 Ivie Road, Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Oral and Written*. Part I. Chicago, Oct. 13-14. New Orleans, Sept. 29-30. New York, Oct. 6-7. San Francisco, Oct. 20-21. Final date for filing application is August 1. Sec., Dr. C. A. Caldwell, 3503 Pryor St., New Orleans.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral*. Chicago, Oct. 4-7. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City, Ia.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Burns Inflicted in Taking Roentgenogram; Technician as Employee of Roentgenologist.—McLaughlin went to the physician defendant, "an x-ray specialist," to have roentgenograms made of his teeth. The physician turned the patient over to a technician in his employ to take the indicated films. In accordance with the technician's instructions, the patient lay on a table, apparently under an "x-ray machine," held a piece of film behind a tooth with his thumb, and moved his head from side to side as the technician directed while the technician moved the machine to obtain the proper angle. According to the patient:

In moving the machine over she hit me here on the finger—right here on that finger, and when she did the fire and the shock all occurred just at one time . . .

The shock seems to have thrown the patient off the table on to the floor and he received burns on his finger, arm and stomach, and his underclothing caught fire. The physician, so the patient testified in the suit he subsequently instituted against the physician, stated, in explaining the incident to him, that "the machine must have come in contact with his belt buckle or tie clasp." From a verdict and judgment of \$2,000 in favor of the patient, the physician appealed to the Supreme Court of Arkansas.

The physician contended, first, that he was not liable for the negligence, if any, of the technician, relying on *Runyan v. Goodrum*, 147 Ark. 481, 228 S. W. 397, 13 A. L. R. 1403. In that case the physician-defendants, Drs. Runyan, Kirby and Sheppard, operated a hospital in which they maintained an x-ray department under the immediate supervision of a physician who was an "x-ray specialist," and this physician had a woman assistant who actually operated the x-ray machine. The plaintiff in that case was burned by the woman assistant and sued Drs. Runyan, Kirby and Sheppard. The physicians were held not to be liable for the negligence of the woman assistant of the "x-ray specialist" on the ground that the relation of master and servant did not exist between them and the woman assistant of the roentgenologist.

The Supreme Court, however, did not believe that the doctrine announced in the *Runyan* case could be applied to the facts in this case. In this case, said the Supreme Court, the physician is himself an "x-ray specialist" and is not a general practitioner, and the patient availed himself of his services because of his reputation for skill and knowledge as a roentgenologist. The patient did not know the technician and relied, not on her knowledge and skill, but on that of the physician. While the technician was doing the manual work of operating the x-ray machine, it appeared that the machine was separated from the part of the office in which the physician was at the time by a partition that did not entirely cut off the physician's view, and the technician was in sight of the physician while she was operating the x-ray machine. The proof established the relation of master and servant between the physician and the technician so as to render the physician liable for injury caused by the technician's negligence. As was said in *Shearman and Redfield on Negligence*, vol. 1, p. 350:

It is an old and thoroughly established doctrine that, where the relation of master and servant exists, the master is responsible to third persons for injuries resulting from wrongful acts or omissions of a servant within the scope of his employment in the master's service.

And, again, in 48 C. J. 1137, this statement appears:

A physician is responsible for an injury done to a patient through the want of proper skill and care in his assistant, apprentice, agent or employee.

The court also cited *Kelly v. Yount*, 338 Pa. 190, 12 A. (2d) 579, in which "an x-ray specialist" was held liable for injuries sustained by the negligence of his assistant, who was a skilled x-ray technician.

The physician contended next that there was no proof that any negligence on his part or on the part of his technician caused the patient's injuries. The technician testified that she was not standing by the table when the patient received the shock but that she was standing at a control cabinet about 6 feet away and that she did not cause the patient to receive the shock by moving the tube, as the patient testified. There was some testimony tending to show that it was improbable that the patient could have received a shock in this manner. The physician argued that the patient raised his hand up in some way about 14 inches and touched the tube, thereby causing the shock. The patient denied this and testified that the electric shock was caused by the technician pushing the tube against him. It was within the province of the jury, said the Supreme Court, to settle the conflict in the testimony, and the jury saw fit to accept the patient's version. Furthermore, it is not denied that the patient did receive an electric shock while he was on the physician's table and that the shock was caused in some manner by the x-ray machine. That being true, it did not devolve on the patient to show the exact cause of the injury. In *Kelly v. Yount*, previously cited, the Supreme Court of Pennsylvania, in discussing the rule as to the burden of proof in a case of this kind, said:

When the thing which causes the injury is shown to be under the management of the defendants, and the accident is such, as in the ordinary course of things, does not happen if those who have the management use proper care, it affords reasonable evidence, in the absence of explanation by the defendants, that the accident arose from a want of care . . .

The court concluded, accordingly, that there was substantial evidence to support the finding of the jury that the patient's injury was caused by the negligent operation of the x-ray machine.

However, the court considered the damages awarded excessive and ordered the judgment reversed and the cause remanded for a new trial unless the patient would consent to a remittitur of \$1,000.—*Gray v. McLaughlin*, 179 S. W. (2d) 686 (Ark. 1914).

Society Proceedings

COMING MEETINGS

National Medical Association, St. Louis, Aug. 14-17. Dr. John T. Given, 1108 Church St., Norfolk, Va., Secretary.
Utah State Medical Association, Salt Lake City, August 24-26. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

- Foreign Bodies In and About the Heart. E. F. Blaud—p. 588
- Cardiovascular System in Traumatic Shock. S. S. Kety and A. Pope—p. 601.

Electrocardiograms from Aviators.—Graybiel and his associates present an analysis of electrocardiographic findings in 1,000 young aviators. This was a highly selected group of men between the ages of 20 and 30 years. None had cardiac defects on physical and x-ray examination. The electrocardiograms were taken with the subject recumbent and, with a few exceptions, in the basal state. The results emphasize great individual variations in the electrocardiographic pattern and a wide range of normal values. Even after rejecting as frankly abnormal some of the extreme values observed, it is apparent that the "normal" extends well into what has commonly been regarded as the abnormal range.

Rheumatic Fever Problem.—Massell and Jones call attention to the close relationship between epidemic hemolytic streptococcus infections and rheumatic fever and point out that rheumatic fever in a given population follows closely the epidemiology of hemolytic streptococcus infections. This pattern is so convincing that it forms the basis of prevention programs. These programs are discussed, with special emphasis on the careful study of respiratory infections from a bacteriologic point of view. Culturing, grouping and typing of such infections offer a key to the streptococcus problem. The use of sulfonamides prophylactically is discussed, and other preventive measures are mentioned.

- Industrial Hygiene in Hawaii. Review of Industrial Hygiene Program of Board of Health. T. L. Schramm—p. 123
- *Novocaine Injection for Low Back Strain. W. L. Argo—p. 133.

"Kissing Bug Bites."—Arnold and Bell report the histories of 2 women who presented a clinical syndrome suggestive of cellulitis with lymphangitis and regional lymphadenitis. Both of them gave a history of being bitten by *Triatoma rubrofasciata*, which belongs to the Reduviidae, whose habits are well described by the lay names of assassin bugs, cannibal bugs and pirate bugs. Their methods of attack may be inferred from the names Mexican bedbug, giant bedbug or kissing bug. The term "kissing bug" has reference to the fact that the bite is usually inflicted on exposed portions of sleeping victims, on the face, and particularly on the lips. The kiss is painless at the moment. It is only after the animal's withdrawal that itching and burning develop, and still later that the painful swelling supervenes along with lymphangitis and lymphadenitis. As suggested by the reviewed cases, shallow incision of the swollen bite site seems to have a favorable effect on the course of the symptoms. The bug's presence in Hawaii constitutes a public health hazard, since it is an important vector of American trypanosomiasis.

Procaine Hydrochloride Injection for Low Back Strain.—Argo says that one of the most troublesome problems encountered in the ambulatory patient, whether military or civilian, is that of low back pain following lumbosacral strain. This type of low back strain usually occurs in the ligaments which resist forward rotation of the upper sacrum: the lumbosacral, the interosseous sacroiliac and the short and long posterior sacroiliac ligaments. Some element of muscular and myofascial strain occurs coincidentally with the ligamentous damage, but in the light of physical examination of the patient it is felt that the clinical picture is referable almost entirely to the ligaments themselves. It has been shown by Badgley and by Steindler that the pain is due to irritation of sensory nerve endings in the ligaments involved. These structures are supplied by the posterior division of the spinal nerve. The most workable concept of the pain in these cases is that of referral, with afferent impulses originating in the damaged ligament being reflexly distributed to other postaxial nerve trunks. The traumatized ligament acts as a trigger point initiating discharge of the pain impulses. This concept is well borne out by symptoms usually presented by the patient and by subsequent disappearance of the pain following breaking of the reflex by local procaine hydrochloride injection as suggested by Kellgren and Steindler. The author describes the technic of injection and the manipulation carried out following it. In 25 of 34 cases treated by this method a single injection was sufficient to effect a cure, with no recurrence after six months of observation. In 4 instances injection was repeated the following day with cessation of symptoms; in 1, recurrence of symptoms after three weeks necessitated an additional injection. In 3 cases in which a rheumatic component was present injections were made for diagnostic purposes and were failures from a therapeutic standpoint.

 *Specific Vaccine Therapy of Chronic Brucellosis. J. F. Griggs.—p. 241.

Vaccine Therapy of Chronic Brucellosis.—Griggs presents an analysis of 100 consecutive cases of chronic brucellosis which were treated with various brucella vaccines and filtrates. The usual forms of brucella vaccine therapy were complicated by the appearance of hypersensitivity in at least 25 per cent of the cases. The author made quantitative studies on the increase in hypersensitivity which is caused by tissue necrosis. He found that increasing hypersensitivity can be avoided and that desensitization is frequently possible if sufficiently minute doses of oxidized brucella vaccine are used (much less than 1 bacterium at first). Clinical improvement follows desensitization, even in stubborn cases which do not exhibit a high skin sensitivity. Desensitization and immunization have given encouraging results when done alternately and repeatedly in the same case. Good results have followed the various methods of specific vaccine therapy in 80 per cent of the cases. Since adopting the improvements reported in this paper, good results have been obtained in 85 to 95 per cent of 200 additional cases.

Histoplasmosis: Report of Case.—A man aged 59 entered the hospital complaining of sores on the tongue and upper lip which had had their onset four months before. The lesions persisted throughout the period of hospitalization. Pharyngeal and laryngeal lesions of a similar character developed with hoarseness and cough. There was remittent septic fever, with excessive fatigue, weakness and loss of weight. All lesions were repeatedly submitted to biopsy. In sections stained by the Giemsa method numerous small yeastlike inclusions were noted chiefly in the reticuloendothelial cells. They could not be definitely identified. The close resemblance of the disease process to histoplasmosis was considered despite failure to substantiate it. The patient received iodides, bismuth, antimony and stibamine glucoside, in addition to sulfanilamide, sulfathiazole and sulfadiazine in full therapeutic dosage for trial periods. Germicidal and parasiticidal solutions were applied topically. The diet was heavily fortified with iron and vitamin concentrates. Radiation therapy was instituted, 900 roentgens being applied to the lip, face and neck fields. Death from cardiac failure ensued six months after the first admission and ten months

after the onset of symptoms. Microscopic postmortem studies revealed Histoplasma capsulatum in the adventitia of the smaller blood vessels in the cortex of the brain and in a few mononuclear phagocytes in the leptomeninges. Histoplasma capsulatum was demonstrated in some mononuclear phagocytes in the granulation tissue of the lingual ulcer. An ulcer at the base of the epiglottis showed an occasional Histoplasma capsulatum organism in plasma cells, lymphocytes and giant cells. Many of the organisms were seen in the lymphocytes, plasma cells and large mononuclear phagocytes in the granulosomatous tissue of the laryngeal mucosa. Large mononuclear phagocytes in the red pulp of the spleen contained Histoplasma capsulatum. The liver showed four bodies resembling Histoplasma capsulatum. Giemsa stained sections of the ureters showed two Histoplasma organisms.

Amino Acid Administration.—Hartmann and his associates employed amino acids ("Amigen") prepared by digestion of casein with pork pancreas in the treatment of 300 patients. Amigen was usually combined with glucose or other solutions. These solutions were used in the treatment of dysentery, diarrhea, pyloric stenosis, intussusception, celiac syndrome, chronic glomerulonephritis, prematurity and many other conditions. Their use orally or parenterally prevents or reduces loss of body protein in children who are unable to derive adequate nutrition from natural foods taken by mouth. When used with glucose and vitamins it makes possible complete parenteral feeding over long periods, as has been shown in a case of tetanus. In combination with glucose and "buffer" solution it is of value in the resumption of enteral feedings in cases of intestinal irritation such as dysentery, "parenteral" diarrhea, peritonitis and postoperative conditions. In the presence of actively functioning kidneys its salt content makes it of some value in the maintenance of acid-base balance. To avoid undesirable reactions it is necessary to be aware of the following limitations: 1. The pH 6.5 solution is relatively more acid than the body's fluids and its parenteral use is not indicated in the presence of untreated acidosis and oliguria. 2. Solutions more concentrated than 3.5 per cent are hypertonic and may be locally irritating. This has not proved an obstacle to the subcutaneous use of more concentrated solutions. 3. Too rapid intravenous administration first produces a facial flush and a sensation of warmth, then a spreading flush over the body, nausea, vomiting and perhaps fever. To avoid this, a slow intravenous drip is recommended. 4. In infants the subcutaneous route is to be preferred to the intravenous one for these reasons: It is vastly easier technically, and the fluid is absorbed at a rate governed by the child's ability to handle it. 5. Concentrated solutions are absorbed rather slowly subcutaneously. 6. Severe dehydration or the presence of a very low plasma protein or a poor peripheral circulation after hydration is a contraindication to the subcutaneous administration of a solution of crystalloids such as the amigen-glucose mixtures.

Influenzal Meningitis.—Lamm and Shulman report 15 cases of Haemophilus influenzae meningitis treated in the pediatric wards of the Kings County Hospital and the Long Island College Hospital during the six year period from 1938 to 1943. Nine of the patients recovered. Of the 6 deaths, 2 occurred in patients who were in the hospital for but seven and fourteen hours respectively. Most deaths occurred among children under 2 years of age. Two cases are reported in detail. In 1 of these

the condition was complicated by agranulocytosis, and in the other a relapse occurred after an apparent recovery. The latter case emphasizes the necessity of prolonged drug therapy. As soon as the diagnosis of *H. influenzae meningitis* was established by a gram-stained smear, blood culture spinal fluid culture or a positive Neufeld's quellung reaction with type specific anti-influenzal rabbit serum, the patients were started on intravenous injections of 5 per cent sodium sulfapyridine. The initial dose was from 2 to 3 Gm, depending on the child's age and weight. When the patients were able to retain oral medication, sulfapyridine was given in periodic maintenance doses. Blood counts and urine analyses were repeated every third or fourth day. Daily urine examinations and blood counts were made when there was evidence of drug toxicity. Within twenty-four hours after admission the patient received from 10 to 15 cc. of anti-influenzal rabbit serum after a negative intradermal skin test. The serum, diluted with isotonic solution of sodium chloride or isotonic solution of three chlorides, to which had been added 1:1,000 epinephrine, was given intravenously. Whenever the patient received adequate amounts of sulfapyridine with a poor response, the drug was changed. Sulfadiazine and sulfathiazole were used as alternates. All patients received frequent small blood transfusions during the critical phase of their illness. Chemotherapy was continued from two to three weeks after the blood and spinal fluid cultures became sterile and the clinical course of the patient was satisfactory, in order to avoid relapses.

Double Ova Pregnancy in Which Rh+ Twin Developed Erythroblastosis.—Potter reports that in May 1943 twins were born at the Chicago Lying-In Hospital to a normal woman aged 32 who had had one uneventful pregnancy nine years previously. The twins were males, the placentas and amniotic sacs were separate. One infant survived and was entirely normal, the other died of erythroblastosis on the second day of life. The mother has shown no anti Rh agglutinins but is OMN Rh—; the father, ON Rh+; the 9 year old daughter, O Rh+; the living infant, OMN Rh— the dead infant, OMN Rh+. It is contended that the father was heterozygous for the Rh factor and that two ova were fertilized, one by a sperm carrying an Rh+ gene and the other by a sperm carrying an Rh— gene. The Rh— mother had been sensitized to the Rh factor either in the previous pregnancy, when an Rh+ fetus had been carried, or possibly during the course of this pregnancy by the Rh+ twin. The antibodies produced in the mother passed through the placentas of both fetuses but affected only the one which was Rh+. The cells of the Rh+ fetus contained the Rh antigen and could be agglutinated by the Rh antibodies; the cells of the Rh— fetus contained no antigen and therefore could not be agglutinated. The fetus whose cells were agglutinated developed erythroblastosis, the one whose cells were not agglutinated remained well.

Causalgia and Gangrene in Meningococcal Meningitis.—Bernstein reports the history of a woman aged 34 who had cerebrospinal meningococcal meningitis. Two unusual complications were present, purpuric dry gangrene of the toes and scattered areas of the skin, and causalgia of the right upper extremity. These complications became manifest after the initial fulminating attack had subsided. The lesions caused protraction of disability for four months. That there was a common etiologic basis for these pathologic changes is uncertain and difficult to maintain. No stained slides demonstrating meningococci were made from either the skin or the toe lesions. The cause was probably a trophic disturbance based on a widespread vascular lesion produced by a peripheral thrombosis or by a peripheral vasospasm from an exotoxin. The pain associated with the gangrene was probably due to peripheral neuritis. The syndrome in the right arm may be attributed to causalgia. The

paradox of severe pain in the arm and hand associated with only minor pathologic changes, and the uncertainty whether the etiologic factor was neurogenic, vascular or psychic, warrant a diagnosis of causalgia.

Vitamin A in Treatment of Hypertension.—Pond and Rosen administered 200,000 units of vitamin A daily to patients with essential hypertension, as suggested by Govca-Peña and Villavieja. There was a gradual fall in blood pressure of 10 patients. The majority of these responded favorably over long periods of time. There were no untoward reactions. Some investigators suggest that the fact that vitamin A in high dosage raises the urea clearance of dogs 40 per cent above normal may indicate that the vitamin may disturb the pathophysiologic pressor mechanisms produced by renal artery constriction. Another possibility is that the anti-hypertensive action of vitamin A may be totally unrelated to its specific vitamin effects and that one or more chemically related compounds with little or no vitamin action may prove to be more effective than vitamin A as hypotensive agents.

*Influence of Gas Mask Respiration on Electrocardiogram and Circulation in Human Subjects. H. Schütz.—p. 739.
Suicide After Cranial Trauma. M. Maire.—p. 783.

Influence of Gas Mask Respiration on Electrocardiogram and Circulation.—Schütz investigated the influence exerted on the electrocardiographic record by breathing through a gas mask in 29 persons between the ages of 20 and 61. Gas mask respiration caused slight changes in all sections of the electrocardiographic curve. The electrocardiographic record taken during rest showed during mask breathing such changes as are observed during mild work. The exertion electrocardiograms differ little whether taken with or without a mask. There were no changes that indicated oxygen lack or coronary insufficiency. Of 15 persons the pulse frequency and blood pressure at rest under the mask indicated that mask respiration requires slightly more exertion than does ordinary breathing. After work tolerance tests the systolic blood pressure showed a considerable increase, but there were no indications of a deficient oxygen supply. Respiration was usually deeper and slower. The minute volume of the respiration during rest was studied on 10 persons with and without a gas mask. The majority showed an increase in the minute volume. Gas mask respiration forces the organism into compensating changes such as are caused by the accumulation of carbon dioxide. Under the gas mask the limits of the reserves will be reached sooner than without the mask. This involves increased dangers for those with coronary defects. Slow and deep respiration decreases the danger considerably because deepening the respiration has a much more economic effect than increasing its frequency.

*Promotion of Climatotherapy in Switzerland by Creation of Climatotherapeutic University Clinics. M. Petitpierre.—p. 661.

Climatotherapy in Switzerland.—The most important successes of high altitude climatotherapy in Switzerland in the last eighty years, according to Petitpierre, have been the open air treatment of pulmonary tuberculosis and heliotherapy of surgical tuberculosis. Climatotherapy is helpful in anemia, particularly when the anemia has impaired resistance. It is indicated in exhaustion due to overwork or infectious foci, in convalescence from serious illness or from surgical operations, and in pleurisy. Climatotherapy has proved valuable in malaria and other tropical diseases. Severe forms of influenza, particularly those accompanied by exhaustion and tachycardia, postpneumonic residual empyemas, dysentery, acute rheumatism, measles and whooping cough, are indications for high altitude climatotherapy. A large number of disorders of the endocrine glands, of the sympathetic nervous system and of allergy are likewise benefited. High altitude climate has a future in heart and vascular diseases. Hypertension of nonrenal origin is one of the indications. Neurasthenia is favorably influenced. Other conditions in which the high mountain climate is likely to be of benefit are osteomyelitis, postoperative empyemas, poorly healing ulcers and bone fractures, conditions in which the local defense powers are deficient. Exudative diathesis, rickets, psoriasis, furunculosis, chronic urticaria and allergic eczemas are favorably influenced. Climatotherapy presents many unsolved questions. The establishment of special clinics for the study of climatotherapy by the Swiss universities is desirable.

*Heredity of Pelger's Nuclear Anomaly. H. R. Schinz.—p. 730.

Heredity of Pelger's Nuclear Anomaly.—Pelger of Holland discovered in 1928 a peculiar blood picture characterized by an abnormal form and structure of the nuclei of the leukocytes. Whereas in the blood of normal persons about

25 per cent of the neutrophils have nonsegmented or bisegmented nuclei and 75 per cent have nuclei with more numerous segmentations, in persons with "Pelger" blood plurisegmented nuclei are entirely missing. In 1932 Huët of Holland established a simple dominant heredity for this anomaly. Persons with Pelger's nuclear anomaly were discovered in many different countries. There are fluctuations in the manifestation of the condition: in persons with the complete Pelger anomaly there are no neutrophils with more than two segments in the nuclei; "half Pelgers" have a certain percentage of neutrophils with trisegmented nuclei. "Full Pelgers" and "half Pelgers" are heterozygotic carriers of the Pelger gene. Schinz points out that in 1939 the Pelger anomaly was discovered in rabbits. Among 400 rabbits, 1 was discovered with a blood picture that corresponded to the Pelger blood picture in human subjects. Breeding experiments revealed that in rabbits too the Pelger anomaly is transmitted as a simple dominant non-sex linked characteristic. The penetrating power of the Pelger gene is 100 per cent. Homozygotic Pelger animals were rare, apparently because of high mortality. When the homozygotic "hyper Pelgers" could be kept alive, it was found that the nuclei of all leukocytes were round and pyknotic; the animals showed extreme developmental retardation; their vitality was greatly reduced; their long tubular bones were shortened and curved. No hyper Pelgers have been observed among human subjects.

Mantoux Tuberculin Reaction.—Egli used Mantoux's test for differential diagnosis of 40 doubtful cases of tuberculosis. Mantoux's method offers the possibility of injecting definite doses of tuberculin. Local, general and focal reactions may thus be prevented. A scheme of the employed phenol solutions of tuberculin is presented. Rise in temperature, depending on the extent of the activity of the tuberculous process, may be associated with a positive skin reaction manifested by a reddened area of 5 mm. or with the next concentrated dose and a local reaction in size from 10 to 30 mm. An eight days curve of temperatures taken prior to and after the tuberculin injection is required. The rise in temperature should be at least 0.3 degrees. Decrease in number of neutrophil leukocytes with rodlike nucleus revealed an obvious parallelism with the temperature test. The temperature test is positive in patients with definitely active tuberculous process. The temperature of convalescents is restored to normal at the same time at which the tuberculous focus becomes inactive. Positive temperature reaction does not occur in definitely healthy persons. In 90 per cent of the author's 40 cases the reliability of the temperature test was confirmed by roentgenologic examination, tomography, artificial pneumothorax, bronchoscopy, bronchography, culture of tubercle bacilli, animal inoculation and other laboratory methods.

*Verrucous Erythematous Lupus: Case. E. Ledo Dunipe.—p. 107.
Hemolysis, New Test. U. Dominguez.—p. 115.

Verrucous Erythematous Lupus.—According to Ledo Dunipe verrucous erythematous lupus is rare. He reports a case in a man of 33 in whom the disease manifested itself shortly after he had become a cow herder. The condition developed slowly, with bouts of aggravation and long remissions. The lesions occupied symmetrical areas near the mouth and on the cheeks, forehead, ears, neck, mastoid region, nose and hands and were intractable. There were hypotension and signs of hypothyroidism. Tests for syphilis and tuberculosis were repeatedly negative. The therapy consisted in injections of bismuth

hydroxide and of local application of solidified carbon dioxide. It was given in series of two weeks, each followed by intervals of two weeks of rest. Local pruritus, infiltration and hyperkeratosis disappeared. The lesions gradually faded, and the horny layer desquamated. After nine months of this therapy the lesions have largely disappeared. The appearance of the skin in the clean areas was that of the skin of very old cow keepers. The author believes that the associated causal factors in the reported case were (1) a constitutional predisposition (2) an organic toxin and (3) a local irritation from prolonged exposure to the sun.

Bilateral Recurrent Benign Spontaneous Pneumothorax Etiopathogenesis J. R. Pazo and J. M. Leston—p. 364

Bone Marrow in Allergic Rhinitis—Erdstein and his collaborators report observations on 16 patients with allergic rhinopathies. The etiologic diagnosis of allergic rhinopathies is difficult. Eosinophilia in the peripheral blood and accumulation of eosinophils in the nasal secretion are not constant findings. An allergic reaction of the bone marrow of the type encountered in all allergic diseases is also encountered in allergic rhinopathies. It consists of an intense local eosinophilia with deviation to the left of the eosinophils, predominance of myelocytes and promyelocytes over that of normal leukocytes, increase in monocytes and plasma cells and phenomena of local toxicity, nuclear irritation, plasma basophilia, vacuolation and coarse granulation. The degree and acuteness of the bone marrow changes vary, but the reaction is present in all cases both during the course of the allergic disease and in the periods of improvement. The bone marrow reaction is of value for the pathogenic diagnosis of allergic rhinopathies as well as for the differential diagnosis of the various types of allergic rhinitis from spasmodic rhinitis and other types of the disease.

Gastrointestinal Ulcers in Children O. Copello—p. 811

Extensive Ulcers of Stomach—Bonomo Pero and his collaborators encountered extensive ulceration of the stomach in 18 out of 1,600 patients with gastroduodenal ulcers. The majority of these patients complained of lack of appetite and loss of weight. The ulcers presented irregular borders in roentgenograms and exceeded 4 centimeters in size. The nature of the ulceration and the therapeutic indications were determined by the therapeutic test, which consisted in putting the patient to bed, a proper diet, antispasmodics and vitamin C. Progressive clinical improvement and diminution of the niche in the roentgenogram indicated a benign ulcer and continuation of medical therapy. Failure of the test suggested cancer and called for surgical intervention. The authors found that cancer is more frequent in niches of the horizontal part of the lesser curvature than of the vertical part of the lesser curvature. Lack of appetite, progressive loss of weight, large size of the niche and irregular borders are of no differential value as between malignant and benign lesions. The therapeutic test is of value in the differential diagnosis and as an indication of the proper therapy.

*Blood Corpuscles in Nutritional Edema in Infants C. Torres Umaña—p. 775

*Familial Chronic Malignant Neutropenia with Atypical Granulations of Leukocytes A. Beguez Cesar—p. 900

Blood Corpuscles in Nutritional Edema—Torres Umaña observed 39 infants with nutritional edema. Hypochromic anemia, moderate leukopenia and a diminution in the number of the blood platelets, of blood albumins and hemoglobin was

encountered in all cases. Some patients presented hemorrhages of the oral mucosa which simulated stomatitis or purpura. The 12 patients with purpura had the lowest figures for blood platelets, with a grave prognosis. Mucosal hemorrhages and purpura paralleled the course of nutritional edema and were controlled in early cases by a diet rich in animal albumins. When nutritional edema runs a favorable course, the blood platelets increase up to normal figures. Purpura of nutritional edema is due to diminution in the number of blood platelets and hemoglobin caused by the insufficient amount of protein in the blood.

Familial Chronic Malignant Neutropenia—The reports by Beguez Cesar are the first of the type to be published. The family of 13 children was the offspring of a married couple of apparently normal and healthy persons. All the children were born at full term by normal deliveries. Nine patients were normal. Four were albinos and exhibited nystagmus. From the age of 2 years the patients began to suffer recurrent febrile attacks of a catarrhal rhinopharyngitis and moderate enlargement of the inguinal, axillary and cervical lymph nodes. The hemogram showed chronic neutropenia, leukopenia, lymphomonocytosis and atypical granulations in the leukocytes. The latter were of a type not previously described. They were encountered in the leukocytes of the father's blood and of all the 13 children but not in those of the mother and her family. The Paul and Bunnell tests for monocytic angina were positive in the patients. The early attacks were controlled by antianemic and anti-infectious therapy, blood transfusions from one of the maternal uncles and a proper diet. The final stage, which occurred between the ages of 4 and 5 years, was of the malignant neutropenia type. The disease is a familial form of malignant neutropenia with atypical granulations of the leukocytes, transmitted by the father and which will probably be transmitted by some of the children.

*Viruslike Infections of Female Genital Organs W. E. Coutts, I. Brieva, J. Lerner and A. Sud—p. 9

Dynamic Indications of Cesarean Section R. Dubrovsky—p. 22

Drumeters Used in X-Ray Measurements of Female Bone Pelvis J. Leon and J. A. Salaber—p. 55

Viruslike Infections of Female Genital Organs—Coutts and his collaborators found that viruses of herpes, nasobuccopharyngeal infections (Broadhurst), inclusion conjunctivitis (Halberstaedter-Thyngerson) and lymphogranuloma venereum are frequent causal agents of viruslike vulvitis, vaginitis and cervicitis. Gynecologic viruslike infections do not react to sulfonamide therapy. A diagnosis can be made from the presence of cytoplasmic, nuclear and tissue inclusions which can be identified in stained vaginal smears or by a biopsy. The differential diagnosis of genital virus infection by the virus of either lymphogranuloma venereum or follicular inclusion conjunctivitis can be established by the results of a skin test in which specific antigens are used. An associated infection may be present.

Leukemia and Pregnancy A. van der Sar and P. H. Hartz—p. 325

*Arterial Fat Embolism Experiments H. Cedeno Perez—p. 340

Arterial Fat Embolism—Cedeno Perez injected sterile olive oil into the renal artery in one group of dogs and into the carotid artery of another group. The dose of oil injected into the renal artery varied from 1 to 2 cc. and of 1 to 10 cc. into the carotid artery. The animals did not manifest general disorders or paralysis. Spontaneous death did not occur during the experiment. The animals were killed at periods varying from ten minutes to fifty days after the injection. The kidneys and lungs of the animals of the first group and the brain and lungs of the second group did not show microscopic lesions of importance. The injected oil passed rapidly (in fifteen minutes) from the renal capillaries into the pulmonary capillaries and still more rapidly (in ten minutes) from the cerebral capillaries into the pulmonary capillaries. The fat accumulated in the

capillaries of the lung was slowly absorbed. The author concludes that arterial fat embolism is not necessarily fatal. It does not produce important lesions. The type of clinical and microscopic reaction produced by fat embolism does not depend on the velocity of the injection of the oil.

*Hematochromatosis Case J. N. Marín and J. F. Ganem —p 1126

Hematochromatosis.—Marín and Ganem report the case of a man 33 years of age, in whom an attack of an acute gastrointestinal disorder was followed by progressive hepatomegaly. A biopsy of the liver taken in the course of an exploratory laparotomy showed that the organ contained a large amount of iron pigment. Diabetes refractory to insulin therapy, asthenia, hypotension, sexual frigidity and progressive emaciation followed. Hematochromatosis appears to be a disorder of iron metabolism in the course of which the cells and tissues of certain organs, especially of the liver, pancreas and endocrine glands, are transformed into depots of iron containing pigment. Destruction of the pigmented tissues and cells and formation of scar tissue follows. Heredity and a familial predisposition seem to play a role.

*Typhoid Intestinal Perforation in Children A. Invaldi —p 417

Postabortion Suppurated Pelviculitis Therapy by Drainage Posterior Colpotomy and Azosulfamide Lavages L. Pasce —p 444

Typhoid Intestinal Perforation.—Invaldi reports 298 cases of typhoid in children. Intestinal perforation occurred in 10 children whose disease was of the grave type. The patients had good hygienic care and a diet of milk and decoctions. Perforation occurred at the level of the ileum during the third week of the disease. The symptoms were sudden pain in the right iliac fossa, which became diffuse over the abdomen within a few hours, abdominal tenderness, vomiting, obliteration of liver dulness, and tenderness in the Douglas pouch on rectal palpation. Increased virulence of *Eberthella typhosa* in certain epidemics is responsible for the occurrence of intestinal perforation. The therapy consists of earliest intervention with suture of the perforations. A single perforation was encountered in 8 patients, three perforations in 1 and four in another. Two patients operated on within six hours of perforation recovered, whereas 6 patients operated on after the six hour lapse died.

Shock and Collapse H. Schwiège —p 765

*Treatment of Fat Embolism with Oxygen Inhalation H. von Brucke —p 771

*Onset and Course of Weil-Felix Reaction During First Ten Weeks of Typhus F. Schutz and T. Messerschmidt —p 772

*Types of Diphtheria Bacilli as Separate Pathogenic and Epidemiologic Entities H. Grossmann —p 774

Dissociated Icterus J. Tako —p 776

Treatment of Fat Embolism with Oxygen Inhalation.—According to von Brucke, passage of fat into the blood stream is a frequent accompaniment of fractures in adults. Blood and urine of patients with fractures contain fat droplets even in the

absence of clinical signs. If large quantities of fat enter the blood stream, pulmonary capillaries may become blocked with fat droplets, with resulting pulmonary fat embolism. There is also a cerebral form of fat embolism. Fat embolism plays a part in the pathogenesis of traumatic shock, for in fatal cases of shock after bone fractures considerable quantities of fat are often found in the pulmonary vessels. The therapy of fat embolism is still unsatisfactory. The efficacy of oxygen inhalation in the treatment of pneumonias induced the author to try this measure in the treatment of a young man with pulmonary fat embolism following fracture of the femur. Various circulatory remedies and a blood transfusion were without effect and the patient's life seemed in danger. After a few minutes of oxygen respiration the color improved, the breathing became deeper and more quiet and the pulse improved. When the oxygen was withdrawn, the condition became worse again and oxygen respiration was resumed. At the end of twenty-four hours the patient's condition was greatly improved. During the following two days the patient breathed oxygen interruptedly.

Weil-Felix Reaction in Typhus.—Schütz and Messerschmidt point out that the Weil-Felix reaction is of great value in the diagnosis of typhus, particularly in its differentiation from typhoid. It seemed of interest to investigate to what titer limit the typhus serum would agglutinate proteus λ 19 bacteria, in which stage of the disease the agglutination titer would be highest and in what manner it would subside. Blood specimens from typhus patients were examined in two different laboratories. In some instances as many as 20 specimens were examined, but the average was 4 or 5 tests in 1 case. The examinations were made between the first and the forty-second day of the disease. Agglutination was considered positive with a marginal value of 1:200 or 1:400. When 1:200 was accepted as the limit, the reaction was positive on the third day in 30 per cent of the cases, on the fourth day in 48 per cent, on the fifth day in 59 per cent, on the seventh day in 65 per cent, during the second week in 91 per cent and during the third week in 99 per cent of the cases. The results are similar when a marginal value of 1:400 is taken as the basis, except that the incidence of positivity is slightly lower. The maximum height of the titer differs in individual patients. Occasionally values of 1:100,000 were reached. The decrease of the titer may be irregular. No satisfactory explanation has been found for these fluctuations. Intercurrent disorders such as colds sometimes caused a temporary renewed increase in the titer. However, if an infection such as a thrombophlebitis greatly depleted the defense powers of the organism, the titer of the Weil-Felix reaction decreased likewise. The reaction became rarely negative again during ten weeks of observation following the onset of typhus.

Types of Diphtheria Bacilli as Separate Pathogenic and Epidemiologic Groups.—Grossmann says that the designation of the types of the diphtheria bacilli as "gravis," "intermedius" and "mitis" was based originally on clinical observations. Later investigators found that the gravis and mitis types do not necessarily correspond to severe and mild courses of the disease and suggested that these type designations be discontinued in favor of the classification types I, II and III. This suggestion was not widely accepted. The author feels that the question cannot be regarded as settled, since the separate pathogenic position of the gravis, intermedius and mitis types may still be relatively correct. The epidemiologic distinctness of the types has also been challenged. Grossmann presents investigations on these problems which he carried out during the years between 1938 and 1940 in 425 cases of diphtheria. He found that the gravis type of the diphtheria bacillus was the one most frequently present in mild cases but in the severe and in the fatal cases it was also found more frequently than the other two. In separating the clinical pictures and also considering the type of bacillus it was found that the gravis type was responsible for the majority of severe cases of diphtheria, the type mitis for most of the mild cases and the type intermedius for the majority of the moderately severe cases. Thus the pathogenic distinctness of the types was relatively maintained.

Book Notices

Oral Histology and Embryology. Edited by Balint Orban. Cloth. Price, \$6.50. Pp. 342, with 262 illustrations. St. Louis: C. V. Mosby Company, 1944.

This is unique among textbooks in that it is written by a number of teachers and investigators in oral histology who collaborated not only by preparing the first drafts for their individual chapter assignments but also by discussing, editing and revising every other chapter. It may therefore be considered to be a careful cross section of the present day views on the various problems in the active field of oral histology and embryology in which different interpretations naturally have arisen in proportion to the rapidity of the advance of this field of knowledge.

The book opens with a discussion of the development of the face and oral cavity, which is supplemented by a number of illustrations including an excellent two page colored plate. Chapter II is concerned with tooth development and lays greater stress on developmental physiology than is usually offered in histologic presentations. The morphologic stages are analyzed in terms of the physiologic processes which they represent and are vitalized by a discussion of the developmental aberrations to which they may give rise.

Chapter III deals with the complex problems of the microscopic structure and development of the enamel. It is the longest chapter and probably the one that gave the collaborators and the editor the greatest challenge. It includes a detailed consideration of the life cycle of the ameloblast, a summary of the latest chemical findings on the calcification of the enamel and a discussion of the submicroscopic structure as revealed by studies in polarized light. This chapter is richly illustrated (one illustration for each page). The chapter on the pulp is excellent and is of special current interest in view of the delicate reactivity of the pulp to changes in atmospheric pressure during flying.

Other chapters cover the fields of dentin, cementum, periodontal membrane, maxilla and mandible, gingival sulcus and epithelial attachment, eruption, shedding of deciduous teeth and oral mucous membrane.

Chapters of special interest and not usually included in histology textbooks deal with the temporomandibular joint, maxillary sinus and glands of the oral cavity. The last chapter deals with histologic technic and includes special methods for the study of the organic structure of the enamel.

A number of the illustrations are of full page size. Some are diagrammatic and help the interpretation of the photomicrographs. In addition there are nine tables which help to summarize and classify some of the facts presented.

The text shows evidence of unremitting care and attention. The technical composition of the book is good. Reading and reference are facilitated by heavy type headings and side headings. Each chapter concludes with a special section on the clinical application of basic histologic data and a selected list of references.

This textbook will be of help not only to the dental student and practitioner but also to the medical student and the physician who is interested in understanding the biologic basis for current theories and various clinical procedures.

Medical Care of the Discharged Hospital Patient. By Frode Jensen, M.D., Instructor in Medicine, Syracuse University College of Medicine, Syracuse, New York, H. G. Weiskotten, M.D., Dean and Professor of Pathology, Syracuse University College of Medicine, and Margaret A. Thomas, M.A. Cloth. Price, \$1. Pp. 94. New York: Commonwealth Fund; London: Oxford University Press, 1944.

This publication reports a study dealing with the problem of providing improved medical care for hospitalized chronically ill patients, and a method of early discharge of ward patients at the University Hospital, Syracuse, N. Y., with follow-up care in the home by a staff physician is described. The need for continuity of medical supervision of patients discharged was shown by the fact that 84.1 per cent of all patients admitted to the medical wards during the period of the study (July 1, 1940 to Feb. 1, 1942) were suffering from chronic disease, and about one third of these had degenerative cardiovascular disease.

Only 59.3 per cent of patients discharged to their private physicians reported to them unless some special step was taken.

Likewise only 23.2 per cent discharged to the outpatient department reported without follow-up. Excessively long periods of hospital care were called for by those patients discharged without referral to private physicians or the clinic.

To study and remedy this situation one of the authors (F. J.) was appointed as extramural resident. Appropriate follow-up in the home was provided for those referred out for further care. For those who were merely discharged home visits were made, and medical treatment as indicated was given in the home by the extramural resident. The percentage of patients who then consulted their private physicians was raised to 78.8, and those returning to the clinic increased to 84.2.

The Home Care Group offered unusual opportunities for coordinating good medical care with the needs of individual patients. Of 165 patients so treated, it is reported that 7,268 days of hospital care at a cost of \$29,072 were saved, independent of the value of the service to the patient. This sum, saved by the services of the Extramural Resident, was three times the total cost of the experiment. What may be of even greater significance is the fact that, by extending the hospital service to include care in the home for but 165 ward patients, beds were made available to serve a possible additional 302 patients with average hospital stays of twenty-four days each.

It is concluded by the authors that the provision of home care for discharged medically needy patients is one further step toward a more economical and beneficial use of the hospital in the care of the indigent.

This short presentation of a study in a field badly in need of suggestions offers interesting and challenging material for further consideration.

Childbirth Without Fear: The Principles and Practice of Natural Childbirth. By Grantly Dick Read, M.A., M.D. Cloth. Price, \$2.75. Pp. 259. New York & London: Harper & Brothers, 1944.

This book was published in England under the title "Revelation of Childbirth." The thesis that Read expounds is that human reproduction is a normal, natural, biologic process. Pregnancy and labor should be conducted in this light. Pain associated with labor is the result of fear engendered by generations of ignorance, misconception and false teaching. The fear of parturition has become the great disturber of the neuromuscular mechanism of labor.

The author removes the pain associated with labor by the elimination of fear. Education during the antepartum period is directed toward impressing the pregnant woman to regard labor as a normal, biologic process devoid of all pain and discomfort. Anxiety is avoided by a careful explanation of all the facts which enter into normal pregnancy and labor. As an adjuvant to this peace of mind, she is taught to relax by systematic exercises introduced at the fourth or fifth month and continued to term.

Labor is conducted as naturally as possible. During the second stage the patient has access to inhalation anesthesia but, if her education has been complete, she will not resort to it. Rubbing of the back and pressure on the sacrum will provide some relief at this period. The relative anesthesia of the perineum which makes it possible for the author to repair superficial tears without anesthesia is due to the trauma to which the perineum has been subjected rather than to the exalted state of the patient at the birth of the baby, as the author suggests. Abnormal or surgical deliveries require anesthesia because real physical pain is induced by laceration and excessive stretching of the birth canal.

There is an excellent lesson in this book for obstetricians and students of reproduction. It is thought provoking as well as interesting to read. Emotional influences do play a profound role in the physiology of reproduction. Pregnancy and labor have come to be regarded as pathologic states. Few women in our large maternities deliver naturally. However, pain relief is here to stay even though the ideal analgesic agent has not been found. In spite of the conversion of a physiologic function into a pathologic state, pregnancy and labor have become increasingly more safe for our mothers and our babies.

The author dedicates this monograph to the late Joseph B. De Lee, a fellow crusader in the interests of safer motherhood, for his kindly interest in his work and his personal friendliness and appreciation.

Female Endocrinology Including Sections on the Male. By Jacob Hoffman, A.B., M.D., Demonstrator in Gynecology, Jefferson Medical College, Philadelphia. Cloth. Price, \$10. Pp. 788, with 181 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

The author set out to give his readers a concise, simple and clear exposition of endocrinology, avoiding the purely speculative and ill founded concepts and emphasizing the sounder views. In this he has succeeded admirably. The book concerns itself not only with the clinical aspects of gonadal and reproductive endocrinology but also with a discussion of the fundamentals of glandular physiology.

In the clinical material, particularly, emphasis is placed on disturbances of functional origin because those make up by far the largest part of all endocrine disorders. Throughout the discussions there is abundant evidence of the author's conservative and critical attitude in the management of endocrine disorders. Likewise, whereas he recounts the vast amount of data derived from animal experimentation, he recognizes the wide gap which exists between laboratory animals and man and therefore he uses great caution in drawing inferences from laboratory research. Laboratory tests and diagnostic aid of other kinds are given in detail for both normal and abnormal patients, and their limitations are pointed out.

The book includes an exhaustive and critical review of the literature on endocrinology. An extensive bibliography is added to each chapter, and at the end of the book is an invaluable bibliographic index which occupies almost thirty pages of double columns. In this index is included every article which is of any importance in the field of endocrinology. For his critical analysis of the vast literature which has accumulated in the last few years, the author deserves special praise because this is a long, time consuming and difficult task. For this job the author is eminently fitted, because he has made many valuable contributions to the field of endocrinology.

The book is written in a style easy to read. The illustrations are abundant and highly instructive. The author is to be highly congratulated on having written one of the best and most useful textbooks on the subject of endocrinology in any language. Likewise the publishers deserve great credit for having done their part magnificently because the paper is excellent, the type is clear and the illustrations have been beautifully reproduced. All in all, this book, which is a treasure house of information, should be in the library of every gynecologist, urologist, laboratory technician and general practitioner.

Supplement to The Extra Pharmacopœia, Martindale, Twenty-Second Edition, Volume I. Published by direction of the Council of the Pharmaceutical Society of Great Britain. Paper. Price, 2s. Pp. 48. London: Pharmaceutical Press, 1943.

The Extra Pharmacopœia, which is published under the supervision of the Council of the Pharmaceutical Society of Great Britain, is widely known. The supplement to volume I, twenty-second edition, contains a summary of changes made in the addenda to the British Pharmacopœia (1932), additions and deletions to the British Pharmaceutical Codex (1934), preparations of the National War Formulary (1943), articles added to and deleted from U. S. P. XII and N. F. VII, some orders in England affecting supplies of drugs, a list with brief description of some new proprietary names not included in volume I, and a few names approved by the General Medical Council for substances of British manufacture which have hitherto been known by other names.

The Story of the First Fifty Years of The Mount Sinai Hospital, 1852-1902. Cloth. Pp. 92, with illustrations. New York, 1944.

This book describes and documents in chronological sequence the story of the formative years of the Mount Sinai Hospital, New York City, from 1852 to 1870, and the subsequent growth and development from 1870 to 1902. A third section is now in preparation and will be published in the *Journal of the Mount Sinai Hospital* as the material becomes available. It is hoped that these reports will also be supplied in book form to complete the historical record of a period of ninety-two years of distinguished hospital service. The book is an interesting narrative of hospital events so written as to reflect the course of medicine in the latter half of the nineteenth century. It introduces many of the prominent physicians of the early period and describes

their work and influence in shaping the medical traditions of Mount Sinai Hospital. Included are many items of special interest in relation to the early history of New York City, its growth and development, the hospital in the Civil War period, character of nursing service, public attitude toward postmortem examination and surgery as practiced in the transitional period of anesthesia and surgical antisepsis. Physicians and hospital personnel will find that this volume yields interesting and profitable reading.

Elementy mysli: Sbornik Izbrannykh statey. [By] I. M. Sechenov. [Elements of Thought Processes.] Paper. Price, 9 rubles, 50 kopecks. Pp. 222. Moskva & Leningrad: Izdatelstvo Akademii Nauk SSSR, 1943.

Sechenov, founder of Russian physiology, was first to attempt investigation of the sphere of consciousness by physiologic methods. He postulated that the thinking process is of reflex nature and that psychic activity of man is therefore susceptible to objective study. He believed that the external world plays an important role in the existence of the living organism. The content of our psychic life is the reflection of the material world in special types of apperceptions, images and concepts. Nearness, distance and height of objects, direction and rapidity of movements are products of our muscle sense. This sense, manifesting itself in periodic movements, becomes the fractional analyzer of space and time. Our numerical concepts stem from the same source. The volume at hand presents a collection of essays by the great physiologist dealing with the development of his central thesis, which is the reflex nature of the process of thinking. The chapters are designated as (1) who is to investigate psychology and how? (2) impressions and reality, (3) elements of the thinking process, (4) objective thought and reality and (5) objective thinking regarded from a physiologic point of view. The volume is one of the scientific-popular series published by the Russian Academy of Sciences. The volume should prove of particular interest to neurophysiologists and to psychologists. It is to be regretted that there are no summaries in English or French.

Introduction to Microorganisms. By LaVerne Ruth Thompson, B.S., M.A., M.S. in Public Health, Instructor of Microbiology, Division of Nursing Education, Teachers College, Columbia University, New York. Cloth. Price, \$2.75. Pp. 445, with 54 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This book is truly entitled "an introduction" and as such can be read by any one with a good high school education. The volume could serve as a supplement to advanced high school or beginning college courses in biology; it may be helpful in introducing the subject to nurses; it will be useful also to any intelligent reader who is anxious to develop or extend an elementary knowledge of biology. The method of presentation employed is rather unusual but its principal feature is the care which has been given to retain accuracy against a background of readily understandable scientific language.

Social and Psychological Factors Affecting Fertility. II: Variations in the Size of Completed Families of 6,551 Native-White Couples in Indianapolis. By Clyde V. Kiser and P. K. Whelpton. Reprinted from *The Milbank Memorial Fund Quarterly*, Vol. XXII, No. 1, January 1944. Paper. Pp. 61-94. New York: Milbank Memorial Fund, 1944.

This pamphlet contains an analysis based on household surveys conducted in Indianapolis of 6,551 native white couples of virtually completed fertility. It is concerned with the distribution and number of live births as related to possible associated factors. The percentage of childlessness, the part played by religion, the relation of family size to rental value and educational attainment and other factors were included. The subject is related to numerous important social and economic problems.

Estudios de histología e histopatología tiroidea. Por Washinton Emilio, profesor titular de histología y embriología de la Facultad de medicina, Montevideo. Paper. Pp. 200, with 96 illustrations. Buenos Aires: Editor "El Ateneo," 1943.

This book represents a review on the correlation between histologic and histopathologic pictures of the thyroid gland and its function. The author has made no attempt to present new material or original concepts. The main value of the book lies on the presentation of a fairly well selected literature on the anatomic changes of the thyroid gland in pathologic conditions. The reproduction of the histologic slides is, as a rule, excellent.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

INTRAVENOUS INJECTION OF FLUIDS AND THROMBOPHLEBITIS

To the Editor—Has there been any evidence to indicate that the intravenous administration of fluids into the leg veins may be a factor in the production of thrombophlebitis and embolism? Has there been any evidence to indicate that the posture of a patient on the operating table, particularly the Trendelenburg position, might influence the production of thrombophlebitis and embolism? If dicumarol is to be used as a prophylactic measure to reduce the possibility of embolism and thrombophlebitis, has anyone outlined a dosage scale to be used in what relation to the date of operation and in what cases should it be used?

Major, M. C. Washington, D. C.

ANSWER—

[This question has been referred to two qualified consultants, whose respective replies follow.—Ed.]

1 Intravenous administration of fluids, provided they are isotonic, hardly ever produces thrombosis in the veins of the legs, it is obvious however, that with many patients harboring small subclinical thrombi in the superficial and perforating veins of the calves a preexisting thrombosis can be stirred up and extended. For this reason, especially in older persons, the use of the veins of the dorsum of the hand or the elbow is preferable, it is known, of course, that thrombosis may occur even in the upper extremities.

Certain postures on the operating table definitely add to the hazards of thrombosis, one of these is the lithotomy position, producing acute angulation of the popliteal vein. The Trendelenburg position accelerates blood flow from the lower extremities and is an excellent method for the prevention of postoperative thrombosis. It certainly does not contribute to stasis and the formation of thrombi.

The use of dicumarol for prophylaxis against postoperative thrombosis and embolism has been reported several times. Butsch and Stewart (*Arch Surg* 45:551 [Oct.] 1942) administered the drug to 23 men one to two days before herniorrhaphy. Excessive bleeding was not encountered and healing was not delayed. Barker, Allen and Waugh (*Proc Staff Meet Mayo Clin* 18:102 [April 7] 1943) used it in 497 surgical cases in which thrombosis seemed likely. In 4 cases thrombosis or embolism developed and in 3 of these it was difficult to secure a satisfactory increase in prothrombin time. Hemorrhage was a complication in 47 of these cases, but it was minor in 29 and moderate to severe in only 18. It was fatal in 1 case.

There are several difficulties encountered in the routine preoperative and postoperative use of dicumarol. Obviously one would select only those patients with types of operations which are known to carry a higher than normal incidence of postoperative thrombosis and embolism. Some of these factors are age over 40, obesity, history of previous thrombosis, operations in the pelvis, lower abdomen or thigh and operations requiring prolonged immobility, just to mention some of the factors. Even in this group many simple measures, such as adequate fluid intake, correction of the anemia, postoperative Trendelenburg position and early mobilization are helpful. Sodium tetrathionate (*Surgery* 14:661 [Nov.] 1943) and neostigmine (*Arch Surg* 48:105 [Feb.] 1944) have been suggested as preventive measures, but their value on a large controlled material is not yet confirmed.

The crux of this important problem is this. If patients could be picked out preoperatively who show a tendency to thrombosis, their intensive treatment with anticoagulants might be logical. Such a test has been suggested (*Surg, Gynec & Obst* 77:31 [July] 1943). Patients showing a poor response to heparin may be given heparin for two days with simultaneous doses of dicumarol. The customary dose of dicumarol is 300 mg the first, 200 mg the second and 100 mg the third day. Unless daily determinations of prothrombin time are available, the administration of the drug is dangerous. The prothrombin time must be kept between 50 and 30 per cent below normal. Experience with operations during the influence of heparin or dicumarol indicate that heparin does not affect capillary contractility and the field is not as vascular as it is when dicumarol is in effect. Dicumarol is not on the market and has not yet been accepted by the Council on Pharmacy and Chemistry.

2 The administration of fluids into the leg veins occasionally is the cause of superficial chemical thrombophlebitis. Since such

a superficial thrombophlebitis practically never metastasizes, it is rarely the cause of an embolism.

The position of the patient on the operating table, particularly the Trendelenburg position, does not influence the production of thrombophlebitis and embolism.

Dicumarol is too dangerous a drug to be given routinely in all postoperative cases. Dicumarol is recommended postoperatively at the first indication of any thrombophlebitic emergency, preferably combined with heparin because it will take dicumarol at least two days to exert an anticoagulative effect. Dicumarol alone is recommended as a routine prophylaxis for patients who give a history of having had thrombophlebitic emergencies following previous operations or childbirth. The initial dose is given on the third day postoperatively unless the surgeon feels that there is still danger of hemorrhage. The initial dose is 300 mg for a patient of over 150 pounds (68 Kg) and 200 mg for a patient under 150 pounds, followed by a daily maintenance dose of 100 mg. A daily morning prothrombin time is essential and the daily afternoon dose of dicumarol is omitted when the prothrombin time has reached 60 to 69 per cent. Each time the morning prothrombin time climbs back to above 70 per cent, another 100 mg of dicumarol is administered. The patient is allowed up according to surgical indications, but only if the prothrombin time is below 75 per cent. When the patient is up the dicumarol is discontinued, there being another four to five days of dicumarol protection before effects wear off.

MENSTRUATION AND PREGNANCY DURING NURSING PERIOD

To the Editor—Do women menstruate while nursing? If so, about what percentage? Is it possible for women who do not menstruate, while nursing, to become pregnant? M. D. West Virginia

ANSWER—Menstruation does occur in many women who nurse their babies. Likewise, ovulation can take place in nursing mothers who do not menstruate, as evidenced by the fact that pregnancy not infrequently occurs during the period of lactation before the return of the menses. Many lay persons and some physicians still believe that breast nursing is a barrier to conception, but many women have learned otherwise from personal experience.

According to De Lee and Greenhill (*Principles and Practice of Obstetrics*, ed 8, Philadelphia, W. B. Saunders Company, 1943, p. 330) the return of menstruation following childbirth varies in different women. In those who do not nurse their babies the menses usually return in six weeks, while in those who nurse their children the first period usually appears after the third or fourth month. In some women, however, the menses do not return until the baby is weaned.

Lass, Smelser and Kurzrock (*Endocrinology* 23:39 [July] 1938) studied 47 normal women during the postpartum period. Each woman was nursing regularly but still having regular periods of catamenia. Endometrial biopsies were taken at four week intervals. From these 47 women 194 biopsies were obtained. It was found that the time of appearance of the first ovulatory cycle was irregular. Of the 194 cycles 106, or 55 per cent, were anovulatory but the rest (45 per cent) were ovulatory, and therefore pregnancy was possible.

Rutherford and Mezer (*THE JOURNAL*, May 9, 1942, p. 124) studied endometrial biopsies from lactating and nonlactating puerperal women. In the former there was definite evidence of ovulation five weeks post partum, and the authors believe that ovulation occurs, on the average, six weeks after delivery. In lactating patients menstruation may be delayed for varying periods, but from the eighth week on the ovarian cycle may escape from pituitary inhibition and render a patient susceptible to impregnation. Therefore the period of lactation is not necessarily a "safe period."

CARCINOMA OF THE VULVA

To the Editor—I have recently removed, with rather wide excision, a tumor which proved to be an adenocarcinoma of the vulva. The pathologist states that all of the tumor was included in the tissue submitted for examination and that it had apparently developed from one of the sweat glands. This small tumor, about 1 cm in diameter, had been present for about six months. It was apparently well circumscribed and was not penetrative in its growth. What further procedures are indicated?

Charles W. Davis, M.D., Humboldt, Tenn.

ANSWER—Carcinoma of the vulva metastasizes to the inguinal glands. The fact that the tumor was thought to be entirely removed does not give assurance that some of the cells have not extended along the line of lymphatic drainage. This patient should therefore receive high voltage x-ray therapy over each inguinal area or have the inguinal glands removed by surgical excision.

ENDOCRINE DISTURBANCES AND ALLERGY

To the Editor—What is the influence of allergy on the Friedman modification of the Aschheim-Zondek test? A white woman aged 40 has a history of several years' duration which strangely suggests allergy. In the remote past she had sinusitis, treated by removal of some intranasal material, possibly polyps. About four years ago she began to have abdominal cramps and diarrhea, and occasional rectal bleeding. Examination at that time included a series of gastrointestinal x-ray examinations, urinalysis, complete blood count, determination of basal metabolic rate, sigmoidoscopy and study of the stool. All tests yielded normal observations. At this time no medication seemed to help the patient and it was finally decided to perform an exploratory laparotomy. This revealed no evidence of disease and no evidence of allergy. The appendix was removed for prophylactic reasons. Following the operation the patient did well for a long time, but eventually the attacks of cramps recurred. This time, however, there was rarely diarrhea accompanying the attacks. Recently the patient reported a new symptom, intermenstrual bleeding, which occurs on slight trauma, such as sitting down at stool. The blood is small in amount but bright red and unlike that seen in menstrual bleeding. The clinical impression was either endocrine bleeding or uterine neoplasm. It was decided to do a curettage for diagnostic purposes to eliminate the possibility of cancer. In such cases I routinely have a Friedman modification of the Aschheim-Zondek test made in the attempt to rule out the possible presence of pregnancy. On attempting this test on this patient 3 rabbits died on two occasions after the injection of the patient's urine. The laboratory reported to me that the rabbits died from anaphylactic shock. I have now begun a thorough allergy work up. I wish to obtain information in regard to the following points: Has uterine bleeding, especially intermenstrual bleeding, been recorded as the result of allergy? Have similar results been obtained before on attempting Aschheim-Zondek tests on allergic patients? Has allergy ever been found to be due to any of the endocrine glands, e. g. ovary or corpus luteum?

M. D., New York

ANSWER—The relationship between the many possible endocrine disturbances to the symptoms of allergy is still one of the unexplored fields. Patients whose asthma was due to specifically known allergens have been completely relieved without any treatment during the period of gestation with recurrence of symptoms during the puerperium or shortly thereafter. Conversely, patients have been seen whose asthma was definitely aggravated during pregnancy. One patient, observed recently, had not required treatment for pollen asthma during the past three years. An arrested case of asthma due to molds and pollens. Shortly after the beginning of her pregnancy she developed severe asthma, which remained throughout her pregnancy. This appeared to be due to the molds and later to three pollens. During the ninth month of her pregnancy, despite the presence of molds and pollens in greater abundance than had been the case the previous few months, the symptoms of asthma subsided quite suddenly and did not recur after the puerperium. The patient had no treatment during all this period of observation. The frequency with which all allergic symptoms are aggravated during the menstrual period or immediately after is well known. However, nothing is known that would conform to the case mentioned in this inquiry. To answer the questions asked: 1 Uterine bleeding, especially intermenstrual bleeding, has not been reported as the result of allergy. 2 No results of Aschheim-Zondek tests on allergic patients such as reported in this query are mentioned in the literature. There would seem to be no reason for reporting the deaths of the rabbits as "anaphylactic deaths" after a first injection of a suspected antigen. It is difficult at times to state definitely that death in a rabbit is due to anaphylaxis. 3 While it is reasonable to assume that disturbances in endocrine function may influence all symptoms, it is not necessarily true that this is due to sensitivity to any of the endocrine glands involved or to their products. "Autosensitization" to injured or diseased tissues in the animal is still in the hypothetical research stage. Sensitization of the animal, whether human or otherwise, to its own normal organs or secretions of organs, is inconceivable since it is incompatible with life.

NEEDLE EMBEDDED IN SACRAL COLUMN

To the Editor—While the Hingson-Edwards method was being used the needle broke accidentally, and x-ray examination shows that it is embedded in the sacral column. The chief concern now is whether the material in the needle may cause electrolytic action which would set up a reaction to the bone structure, the needle referred to is made of number 8 stainless steel with about 18 per cent chrome and 10 per cent nickel. There is also the possibility that the needle may work itself through the bone structure into the tissues of the nervous system.

M. D., New Jersey

ANSWER—It should be determined by the roentgenologists whether the needle is in the hollow canal of the sacrum or whether it is posterior or anterior to the sacrum. It is the writer's opinion that this needle should be removed as soon as possible. It may travel, but especially it may become associated with an infection and abscess formation, and this may become

multiple. This same accident has occurred elsewhere, and once a needle was left in place for eight days a small abscess developed. In another case a needle was removed within two days and no infection resulted.

LOCAL ANESTHETIC INJECTIONS FOR SPRAINS

To the Editor—Since reading Lieutenant Commander McMaster's article on ankle sprain in *The Journal*, July 3, 1943, I have been trying this method on a few patients. I have also used it in cases of sprain of the lateral ligaments of the knee joint. I have been using 2 per cent procaine with epinephrine, although the article specifies this same strength without epinephrine. I find that there is immediate relief, of course, but when the effect of the local anesthetic begins to wear off in a short while the pain is frequently worse than ever, requiring sedation in most cases. Would the addition of the solution of epinephrine hydrochloride (1:50,000) make this occur? If so, why? Is there any more danger in using the procaine without epinephrine than with it?

M. D., Ontario

ANSWER—In the original article (*Press med* 40:280 [Feb 20] 1932) Leriche used procaine 2 per cent for injection of sprained ligaments about the ankle. No mention is made of the use of epinephrine. As this was originally Leriche's method and it does relieve the pain of a sprained ankle, sometimes permanently, there is no reason for the addition of epinephrine. There is also no reason why the use of epinephrine should cause the pain to recur unless the return of blood to the ischemic area produced by epinephrine may cause painful pressure. The action of epinephrine in local anesthesia is to cut down the blood flow in the area and thus keep the anesthetic localized and retained longer, possibly prolonging its action. The danger of the general action of procaine might thus be lessened. However, in using Leriche's method of ankle injection it would be well to follow the letter of his technique until some changes should be proved better. The same rule applies for every one who uses a given technique devised by an expert and is especially true in the case of an occasional user, as in Orr's method of treating osteomyelitis or compound fracture, the Carrel-Dakin treatment of wounds, the Lane technique or the Hobart operation for recurrent dislocation of the shoulder.

HIGH ALTITUDE FLYING AND IMPOTENCE

To the Editor—Will you kindly advise me whether frequent high altitude flying bears any causal relation to male impotence? M. D., New York

ANSWER—There is no reason to believe that high altitude flying per se has any causal relation to male impotence.

The use of oxygen nullifies the physical effects of altitude up to 34,000 feet and to a decreasing degree above that level. Except for combat flying, planes rarely go above that altitude and usually not nearly that high. Flying for long periods repeatedly at moderate altitudes of 12,000 to 18,000 feet without oxygen results in the development of chronic fatigue and a gradual lowering of the ceiling of the individual. This chronic fatigue might be a factor in the development of impotence. It is recognized that all pilots should use oxygen above 10,000 feet and some authorities advise its use for prolonged flights above 8,000 feet. With this precaution there should be no deleterious effects from the altitude itself. Regardless of altitude, however, flying long hours without adequate rest periods, especially flying under conditions of stress, often results in the development of a condition known as acroneuriosis. This condition might lead to temporary impotence.

APPENDIX IN LEFT LOWER QUADRANT OF ABDOMEN

To the Editor—In what percentage of cases is the appendix found in the left lower quadrant of the abdomen?

Lloyd J. Netto, M. D., West Palm Beach, Fla.

ANSWER—The percentage of cases in which the appendix is found in the left lower quadrant of the abdomen is not known. An estimate would be that it is between one tenth and one hundredth of 1 per cent. It may be due to an unusually long mesentery, to arrested fetal development or to transposition of the viscera.

NATURAL SULFUR WATER AND PEPTIC ULCER

To the Editor—Is natural sulfur water as drunk at various springs contraindicated for persons who have peptic ulcer?

F. H. Hodges, M. D., Pikeville, Ky.

ANSWER—Evidence to support the supposition that sulfur water from natural springs is contraindicated in persons who have peptic ulcer has not been found. The possibility of formation of sulfuric acid is too remote to be of any significance.

NATIONAL PROGRAM FOR PHYSICAL FITNESS

REVEALED AND DEVELOPED ON THE BASIS OF
13,000,000 PHYSICAL EXAMINATIONS OF
SELECTIVE SERVICE REGISTRANTS

COLONEL LEONARD G. ROWNTREE, MED. RES.
Chief, Medical Division, National Headquarters, Selective Service
System; Vice Chairman, National Committee on Physical Fitness,
Federal Security Agency
WASHINGTON, D. C.

Medicine has played an indispensable role in the creation of our armed forces. For nearly four years, doctors have been examining and passing judgment on innumerable thousands of registrants. By January of this year more than 13,000,000 examinations were completed. This unprecedented mass of medical data is now being subjected to statistical analyses. Both in quality (medical procedure and judgment) and in quantity (numbers involved) this material far surpasses that of any other survey ever made in the history of our nation.

While the primary objective of these examinations was for the selection or rejection of men for the military service, there has emerged as a by-product a picture of the health needs of the nation. The knowledge of the medical profession about the physical state and health of the American people has been widened and deepened by the Selective Service experience. Perhaps in no other way could this end have been obtained. The medical profession, in doing this work itself, has itself acquired the knowledge, has revealed the national needs, and now it must come forward with a program to meet these needs. Medicine, in a spirit of service, in a great and effective way, has helped to create our military establishment and has aided fundamentally in solving the whole war manpower mobilization problem and visualized as never before our health needs. Now that medicine has the diagnoses, remedy should be suggested and treatment begun.

In the beginning, the Selective Training and Service Act of 1940 was designed to provide the authority for the leisurely procurement of an army for national defense. This was most fortunate, since it afforded Selective Service an opportunity for orientation in numerous fields prior to the great pressure for manpower that followed the declaration of war. As since amended, the act provides for the wartime control of the allocation of manpower for both military and civilian needs: Procurement, on the one hand, through selection of the maximum number of qualified men needed by all the branches of the fighting forces for the successful

prosecution of the war; and, on the other hand, for war production through selective deferment of sufficient numbers of skilled workers in industry and agriculture, to provide all the necessary sinews of war and also sustenance for ourselves and our allies.

The dual function has imposed on Selective Service the need for frequent changes in policy to meet the constantly shifting demands for troops for service and for manpower in the production of food and armament at home and abroad. Regulations have had to be amended from time to time to meet changes in policy.

In the beginning the pool of manpower loomed great, so enormous that it seemed inexhaustible. However, as the various and expanding demands were met, it became apparent that only through the wisest allocation of manpower could the national objective be fulfilled. Major adjustments became imperative in matters relating to marriage, fatherhood, dependency, agriculture and essential occupations. Throughout it all the Selective Service System has striven to maintain an optimum balance in the supplying of all the various needs as defined by national objectives. General Hershey has guided Selective Service with a masterly hand.

THE MEDICAL FUNCTION OF SELECTIVE SERVICE

In five registrations between Oct. 16, 1940 and July 30, 1942 all the males between 18 and 65 years of age have been registered. Twenty-nine million fall between the ages of 18 and 45 but only 22,000,000 men, those between 18 and 37 years of age, are subject to induction. It is the function of Selective Service to classify all men within the 18 to 45 year range, and it is the function of the Medical Division to advise the local boards as to the physical requirements for acceptance into the fighting forces. It is in this connection that medicine has given freely of itself and has done a stupendous and magnificent job. In this program some 33,000 doctors and 10,000 dentists have participated as examining physicians attached to local boards or as members of the medical advisory boards. All such service has been gratuitous. In addition, civilian doctors have constituted the backbone of the examining groups at the armed forces induction stations.

In Selective Service, medicine has functioned at the national, state and community levels. The working unit is the local board, in which is centered the responsibility and authority for classification subject to appeal. Of such there are now 6,441, virtually all with one or more physicians attached. In addition, the medical advisory boards, now some 812 in number, have rendered expert medical judgment through their 8,000 to 10,000 members. The state medical officers, one or more in each state, coordinate the medical work of the local boards within the states and also serve as chief medical liaison officers between national and state headquarters.

The results of all medical examinations have been recorded on special forms provided for the purpose

(in the beginning form 200, subsequently form 221). Copies of all completed forms, more than 13,000,000, have been filed in the Philadelphia branch of the Division of Research and Statistics of the Selective Service System. Thus it is possible for appropriate authorities to obtain at will the record of any individual registrant provided he is properly identified.

The Changing Nature of Selective Service Examination.—In the beginning the examining physicians of the local boards were called on by the regulations to conduct a complete physical examination of all registrants classified as 1-A. This included the collecting of blood for serologic tests and also urinalysis and, in most instances, blood pressure readings. These physicians were urged to reject registrants or send them forward to the armed forces induction stations only when certain of their ground; otherwise to refer them to the medical advisory boards for more expert examination and judgment.

In the beginning the physical examinations were conducted by the local board examining physicians in their own offices as a rule. As time passed there developed a constantly growing tendency for the physical examination of registrants to be carried on by groups of physicians working in teams or groups at hospitals rather than as individual doctors working in their own offices. While the office examination usually required from forty to fifty minutes per man, it was found that the work could be more effectively handled by groups, reducing the time required for each registrant and simultaneously improving the quality of the examination. To a very great extent certain phases of the medical function of Selective Service were centered in hospitals located in large and medium size cities. Not only were doctors and dentists participating in this development but also considerable numbers of volunteer workers, including nurses, interns, medical students, legionnaires and others. As the result of this assistance, Selective Service was benefited immeasurably and the examination of registrants expedited.

The groups of registrants examined varied greatly in size, according to the number of local boards concerned and the quarters, facilities and personnel available, in some instances involving small numbers of 20 to 30 registrants and 2 to 4 medical examiners, and in others large groups of 100 to 200 men with 10 to 20 physicians. Many of these group examinations were efficiently organized and furnished unusually expert medical judgment. Under such conditions the medical personnel were unusually enthusiastic. However, individual examinations still prevailed throughout the nation with faithful service from thousands of examining physicians. This, in principle, briefly covers the medical function of Selective Service up to the present.

As time went on, it became apparent that some change would be necessary. As the ranks of the Medical Corps of the Army and Navy swelled, the ranks of available physicians for the Selective Service function were rapidly diminishing. In consequence, three possibilities for curtailment of doctors' hours were pilot tested in three different states: Pennsylvania, involving a preinduction examination; Ohio, omitting physicians in the medical examination; and Indiana, involving a preinduction examination, with a coarse screening of manifestly disqualifying defects by the local board examining physician.

This experience furnished the basis for the national adoption of the Indiana plan when the need for change

on a national scale became definitely established. The fixed authority of the Surgeons General of the Army and Navy for final selection, and the diminishing ranks of available physicians for local board service were the two most important determining factors back of the change. The present system, of which the collecting of blood for serologic examinations is also taken over by the induction stations, is born largely of necessity—the relative unavailability of physicians, chiefly in rural districts, and the pressing need of the civilian population for medical care. All changes have been effected with prior understanding of the Army and the Navy.

SOME OF THE MAJOR MEDICAL PROBLEMS ENCOUNTERED

Psychiatry.—Difficulties in this field were early anticipated for reasons that are obvious. In fact, Dr. Winfred Overholser, the medical director of St. Elizabeth's Hospital, Washington, D. C., wrote the President in August 1940 suggesting the need for special provision in this field. As a consequence an Advisory Committee on Psychiatry was created and an adviser to the Director on Psychiatry appointed. A national program of seminars was conducted for indoctrination purposes, and Medical Circular No. 1 on psychiatry was published for the guidance of psychiatric examiners.

Despite these efforts it soon became apparent that selection was faulty: that men were inducted who should have been rejected, thus resulting in high rates of discharge in the neuropsychiatric field. It was suspected that many were being rejected who might have been able to serve to advantage. As a result many other measures had to be adopted by Selective Service and by the military authorities to cope with the problem. Among them was the nationwide Medical Survey Program now in operation. This will be discussed in some detail later.

Dentistry.—The rate of rejections for dental defects has been very high and was on the increase rather than on the decrease. Because of this high rate of rejection a Dental Advisory Board was established at National Headquarters under the leadership of Dr. C. Willard Camalier, and Commander (now Captain) C. Raymond Wells, D.C., U.S.N.R., and president of the American Dental Association, the latter becoming chief dental officer of the Medical Division. This group outlined the needs of the examination and provided both personnel and facilities for the local boards throughout the nation and issued Medical Circular No. 2 (dental). As the result of their efforts, some eight to ten thousand examining dentists were added to the uncompensated personnel of the Selective Service System.

The rejection rate, however, continued high, so high that it became necessary eventually for the armed forces virtually to abolish dental standards, to accept men with dental defects and to rehabilitate them within the military services. The work of the dentists was very satisfactory, and their cooperation was splendid.

Syphilis.—Through the wisdom and cooperation of Dr. Thomas Parran, Surgeon General, the United States Public Health Service has made serologic tests on all registrants to date. It has served a most useful purpose, primarily in identifying those men afflicted with syphilis and revealing the magnitude of the problem of venereal disease to the nation. Statistical analyses disclosed that, of the first 2,000,000 registrants, positive or doubtful serologic reactions were encountered in 47 men out of every thousand examined. Because of the

numerical importance of venereal disease and the failure on the part of society to rehabilitate the syphilitic, their induction became imperative. The syphilitic have been taken into the service as rapidly as facilities for their treatment would permit.

Illiteracy.—Distasteful as it is, it must be admitted that illiteracy exists widely throughout the nation. Of the first million rejectees, 100,000 were disqualified because of illiteracy. The number of rejectees continued to mount until the military authorities were compelled to induct the illiterate and educate them in the service.

Hernias.—The military authorities are adverse to the induction of men with hernia except the small symptomless variety at the umbilicus. Early in the war period, hernia was accepted by the Navy and subjected to repair. Part of the difficulty in the repair of hernia, under compulsion, is the psychic trauma which results in painful scars and functional disability. Only after the hernia "pool" reached more than 200,000 were they found acceptable. At present all registrants with inguinal hernias are subject to induction except those descending into the scrotum. Within the Army the hernia victims are either operated on or carried under limited service. Hernias are included in the daily limited service induction quotas.

The President's Plan for Rehabilitation of Registrants.—Because of the unfitness for service of 50 per cent of the registrants examined and the urgent need of manpower for the armed forces, the President in October 1941 suggested a plan for the rehabilitation of as many registrants as possible. His plan provided that 200,000 at least be rehabilitated, under the auspices of Selective Service and its nationwide network of boards, that the rehabilitation be carried out in the registrant's home community by Selective Service in conjunction with the local county medical and dental societies and that this be effected at a reasonable cost for which adequate funds would be forthcoming.

Obviously this problem was extremely complex. It called for good judgment as well as adequate remedial measures and for cooperation on the part of all those interested in the healing art. In consequence, a meeting was called by Selective Service at National Headquarters, bringing together representatives of the schools and hospitals, of the American Medical and Dental Associations, of the Defense Health and Welfare Services to the War Manpower Commission, of the Council of National Defense and of certain federal and social agencies. The problems of rehabilitation were thoroughly discussed and, to some extent, the interest and the role of each and all of these organizations defined.

Army experience teaches that only certain types of cases are susceptible of satisfactory rehabilitation. In consequence, it was decided to limit rehabilitation to these types. In conference with the Surgeon General, it was further determined to limit rehabilitation to registrants who could be certified by the Army in advance as acceptable on completion of the rehabilitation specified. This plan obviously eliminated all waste effort and expense and limited rehabilitation to those who could subsequently be accepted into the military forces.

Shortly after the rehabilitation program was suggested the Japs made their attack on Pearl Harbor. As a result, the pressure for fighting men became extreme, and most of the registrants scheduled for rehabilitation were inducted in status quo and without

the correction of their defects. The plan was pilot tested later in Maryland and Virginia. The results were relatively meager. General Hershey decided therefore not to continue the plan but turned the whole problem over to the War Manpower Commission, which had been created in the interim.

PREHABILITATION

The President's plan provided for the rehabilitation of 200,000 men for service with the armed forces. It did not, however, solve the much greater problem of the lack of physical fitness and the prevalence of deficiencies and defects among other men of military age or among the civilian population as a whole. In this connection Selective Service offered its own plan, the plan of prehabilitation, which provided for a campaign of education concerning the standard requirements in the Army, the examination by the family doctor or dentist of those men who fall short of these requirements, the correction of remediable defects found by the doctor or dentist concerned on the usual doctor-patient relationship and the certification of prehabilitation by the doctor responsible for the correction of the defects.

This plan invited every registrant and every young man in the nation to fit himself in advance for examination and, if acceptable, for service with troops or industry. It emphasized the desirability of not permitting minor defects to defeat major objectives. It is particularly applicable in universities, colleges and schools all over the country, as also in labor and industry. The fact that defects are prevalent, as evidenced by the surveys of Selective Service, indicates a widespread need for improvement in physical fitness and health. This campaign accomplished much, particularly in making the nation conscious of national health needs and in laying the foundation for programs for physical restoration and physical training and for programs of prevention.

WARTIME SELECTION

Originally, Selective Service was concerned in the procurement of men for a peacetime army of moderate proportion and of slow growth and expansion. With Pearl Harbor and the declaration of war, came:

(1) the need for immediate and unprecedented expansion with a pronounced increase in the rate of induction;

(2) the immediate lowering of the physical requirements for induction, in some instances temporary in nature;

(3) the use of 1-B men (limited service) by the Army;

(4) a change in the character of examination for induction both by Selective Service boards and by the Army;

(5) abolishment of enlistment by the Navy, and Selective Service procurement for the Navy;

(6) the correction of certain physical defects within the military establishment, and

(7) the extension in the age range of those acceptable for military service, 18 to 38, as contrasted with 20 to 28 in the pre-Pearl Harbor period.

The advent of war resulted in a movement to increase the tempo of Selective Service and to enlarge the registered manpower pool to its maximum strength as rapidly as possible. The fourth registration, on April 27, 1942, required men between the ages of 45 and 65 to

register, and on June 30 of the same year persons between the ages of 18 to 20 were requested to register. In December 1942 inductions were limited to men of 18 to 37 years inclusive.

In August 1942 classification 1-A (r) (remedial) and 1-B (limited service) were eliminated, leaving IV-F as the only classification for registrants disqualified for general military service.

Dual v. Single System of Examination.—From a medical point of view the most important change concerned the type of medical examination given registrants by the local board examining physicians. With the final responsibility resting in the Office of the Surgeon General for a complete physical examination and the decided expansion of medical personnel in the Medical Corps of the Army and Navy, and because of increasing difficulty in obtaining adequate numbers of local board examining physicians, the Selective Service local board medical examination was abolished. In its place was substituted a preliminary physical examination, a screening test, whereby only those registrants with manifestly disqualifying defects were rejected. These defects were listed on D. S. S. form 220.

The fundamental change in procedure elicited varying reactions: satisfaction in areas where medical service was difficult to obtain; dissatisfaction and to some extent resentment, where medical services were still available. However, in the course of the next six months the new system was found generally acceptable. Notwithstanding the changed procedure, group team examinations still continued in larger centers. In Chicago and New York it culminated in mass examinations involving, in some instances, as many as 1,000 to 1,200 registrants per day.

As a result of the changed procedure and the increasing inductions, the relative rejection figures from local boards and induction stations underwent reversal. Under the final type of examination given on local boards, it was found that Selective Service was responsible for 41 of the 50 per cent rejections. But, under the screening examination, with the final examination given by the armed forces, Selective Service is responsible now for rejections of only 5.6 per cent of the 46.9 rejection rate during December 1943.

Throughout the first three years of existence, Selective Service continued to collect blood for serologic tests for syphilis. Selective Service discontinued this practice in the early months of 1944 and the collection of blood, as well as serologic tests, is now made at the induction stations.

Beginning in January 1943 Selective Service procured men for the Navy as well as for the Army. Enlistment, except under 18 and above 38 years of age, was prohibited.

Lowering the Standards as the Result of Need for Military Manpower.—The standards for admission to the fighting forces are established by the War Department (more recently after conference with the Navy) and adjusted from time to time to create the maximum possible available manpower pool. The level of the requirements depends on the number of men needed in the military services, the urgency of need, the size of the overall manpower pool and the relative need for men for military service and for production. Selective Service attempts at all times, through proper adjustment, to maintain the optimal balance in meeting manpower needs for national objectives.

Special Provisions for Selection in the Neuropsychiatric Field.—The most difficult problem of selection is in the field of neuropsychiatry. Many plans have been tried and an infinite number of possibilities suggested. The most important steps taken by Selective Service and the armed forces are as follows:

1. Provision in D. S. S. form 40 for the registrant's own statements relative to present or past mental difficulty.

2. A course of indoctrination, which was given in the early days of Selective Service through an educational campaign of seminars, and Medical Circular No. 1.

3. The local board judgment based on knowledge or information acquired locally or through the local board examining physicians.

4. The local board preliminary physical examination conducted by the local board physicians.

5. Provision for information to the local board by affidavits from physicians or statements of governmental agencies.

6. The Selective Service program covering the assembling of pertinent information, as set forth in section 623.33 (e) of the regulations.

7. Examination at the armed forces induction station

8. Observation period of three days at the discretion of the armed forces examining board. This period may be too brief in some instances. Perhaps it could be extended to advantage—a view stated a year or so ago by Dr. R. D. Gillespie on his visit here from England.

9. After rejection by the armed forces, a special review of findings by a medical advisory board if considered indicated and requested by the local board.

Medical Survey Program.—Despite all the various devices, rejection rates and discharge rates for nervous and mental diseases have still continued unduly high. The problem loomed very serious. In February 1943 a letter was received by the director of Selective Service, Major General Lewis B. Hershey, from the Secretary of War, Henry L. Stimson, outlining the difficulties and calling on Selective Service for a special program whereby information concerning registrants, pertinent to selection or rejection, should be assembled locally and transmitted to the psychiatrists on the induction boards for their guidance in arriving at decisions.

As a result, a national program has been developed. It involves the appointment of special advisers to each state director and the appointment of several thousand medical field agents, one or more to each local board, for the assembling of information, much of which is obtained from existing social and welfare agencies, the files of penal institutions and the like. Information is also obtained from school teachers or school records. Forty-six states now have some such program in operation; 8,000 medical field agents have been appointed. The program has the backing and support of the War Department, the Surgeons General of the Army, of the Navy and of the U. S. Public Health Service, and the U. S. Commissioner of Education. The program is well under way under the efficient coordination of Lieut. Col. Louis H. Renfrow and Dr. R. W. Waggoner.

The Present Size and Composition of the 4-F Pool.—It seems desirable at this juncture to consider the size and composition of the 4-F pool as it exists at present. This furnishes a much needed perspective. The 4-F pool has grown steadily during the past year

at a net rate of approximately 85,000 per month. This has continued despite the drastic lowering of standards, which has included among other changes the induction of limited numbers of men with uncomplicated venereal disease, with hernia and illiterates, and large numbers of men with dental defects. The size and composition of the 4-F pool at present is shown in the accompanying table. The age distribution in this group is of special interest; as of March 1, 1944 there were 1,400,000 under 26 years of age, approximately 700,000 between the ages of 26 and 30 years, and 1,400,000 between 30 and 38 years of age. Above 38 years of age, experience has shown that there are few that can qualify and serve satisfactorily. Above 38 years the rejection rate is over 60 per cent and the discharge rate unusually high.

Preponderance of Psychiatric Rejections.—Attention is called to figures presented on rejections: for mental disease 657,100, or 16.2 per cent; for mental deficiency (including illiteracy) 563,300 or 13.9 per cent; for neurologic disorders 208,600, or 5.1 per cent, totaling in these categories 1,429,000, or about 35 per cent of the grand total of the rejected.

The picture as a whole shows that of some 13,000,000 examinations given there are still approximately 4,000,000 rejectees, despite the lowering of standards and all the rehabilitation that has been carried on throughout the nation. In addition, the discharge rate continues high. More than a third of the rejections are for neuropsychiatric reasons.

The question arises as to whether psychosomatic disease should be included in this category. They are closely related in many instances at least. They represent the visceral expression of disease, functional or organic in nature, rather than nervous and mental diseases per se. Selective Service figures revealed an unusually high incidence of psychosomatic diseases in peacetime selection, especially in the white. The incidence of neurocirculatory asthenia was 6.7 times as great in the white as for the Negro, and for peptic ulcer ten times greater. The effect of war has greatly increased the incidence of psychosomatic diseases in the Negro, who in peacetime appeared relatively immune. As a result, it can be stated that the psychosomatic disorders are appearing in increasing frequency in the Negro as well as in the white population.

Lack of Physical Fitness and Need for Physical Training.—Not only do the defects, deficiencies, disabilities, disorders and diseases abound, but, in addition, many of the registrants were found to be pampered, soft, flabby and in need of conditioning. Special training in physical fitness was necessary, after induction, which represented weeks of wasted time and effort which could have been avoided if every young man prior to induction had made himself physically fit.

Lack of physical fitness prevailed among the youth of the country because the nation failed to recognize its importance and because youth itself failed to earn fitness. Where does the fault lie? The present situation is the result of indifference and apathy on the part of the government, states, municipalities, parents, teachers, churches, the medical and dental professions, the U. S. Public Health Service and, to a certain extent, of youth itself. It is in a large measure failure in our education system and our homes. The failure is a combined one; youth is the victim. Only concerted efforts of all those concerned in the failure can

bring about the cure or, what is still more important, prevention for the future.

Physical fitness is a matter of development. The attributes essential to success in war and combat are strength, endurance, stamina, special abilities, leadership, initiative, emotional stability and the indomitable "will to win." Physical fitness is the bodily state which combines maximum power and efficiency, with the minimum time for recovery after exhaustion. It cannot be acquired overnight. It is a matter of evolution. It calls for time and for graded training in the development of the body and mind to maximum efficiency.

Estimated Principal Causes for Rejection of Registrants 18-37 Years of Age in Class IV-F, as of May 1, 1944

(Preliminary)		
Principal Cause for Rejection	Number	Per Cent
Total.....	4,049,000	100.0
Manifestly disqualifying defects	425,700	10.5
Mental disease.....	657,100	16.2
Mental deficiency*....	563,300	13.9
Physical defects....	2,345,200	58.0
Musculoskeletal.....	308,500	7.5
Syphilis.....	286,800	7.1
Cardiovascular.....	261,600	6.5
Hernia.....	220,000	5.7
Neurologic.....	208,600	5.1
Eyes.....	206,100	5.1
Ears.....	156,100	3.9
Tuberculosis.....	107,700	2.7
Lungs.....	69,600	1.7
Underweight and overweight	60,700	1.5
Feet.....	51,700	1.3
Abdominal viscera....	50,600	1.2
Kidney and urinary....	41,900	1.0
Varicose veins.....	40,700	1.0
Genitalia.....	40,400	1.0
Endocrine.....	38,800	1.0
Teeth.....	35,800	0.9
Skin.....	24,900	0.6
Neoplasms.....	24,900	0.6
Nose.....	24,300	0.6
Gonorrhea and other venereal diseases	18,200	0.4
Hemorrhoids.....	16,500	0.4
Mouth and gums.....	11,000	0.3
Infectious and parasitic.....	4,200	0.1
Throat.....	4,000	0.1
Blood and blood forming.....	3,600	0.1
Other medical defects	23,800	0.6
Nonmedical defects.....	57,700	1.4

* Includes registrants rejected for educational deficiency before June 1, 1943 and for failure to meet minimum intelligence standards after that date, as well as those rejected for mental deficiency.

Source: Forms 110, 111, 140A and 221

The President Creates a National Committee on Physical Fitness.—So important loomed the problem that in 1943 the President created a national committee on physical fitness under theegis of the Federal Security Agency and the chairmanship of Mr. John B. Kelly. This committee has worked assiduously in the field and from its national headquarters in Washington to educate the public concerning the present situation and to indoctrinate the people with a consciousness of the national need for conditioning. The committee has published many brochures and has aided many groups here and there in every state in the Union to set up the machinery whereby physical fitness may be attained. In the brief space of a year it has interested many national leaders and has harnessed together the interests and efforts of more than 150 national organizations that come in contact intimately in one way or another with the problems of fitness.

However, the committee has found that a great national movement for greater physical fitness awaits vigorous medical leadership. Hence this committee is bringing its problem to the American Medical Association and requesting the medical leadership essential to success.

CONSTRUCTIVE PROGRAM FOR PHYSICAL FITNESS

A Challenge to Medical and Social Leadership.—The amazing conditions revealed by the Selective Service statistics, as to the physical fitness of the nation, is a challenge to the medical profession particularly and to all interested in national health and national morale, and in the future of the nation and its youth. The conditions call for both a remediable and a preventive program. Everything should be done that can be done to improve the surprising conditions that have been revealed, and more must be done to prevent similar conditions developing in the rising generations.

The Need for the Leadership of the Organized Medical Profession.—This is a problem that not only requires the sponsorship and devoted efforts of individual medical men but calls for more: the organized sponsorship and support of the profession of medicine. The need for such sponsorship, leadership and support is recognized by the present National Committee on Physical Fitness of the Federal Security Agency, and it looks to the organized profession of medicine not merely for help but for active participation and assistance in the direction of the movement for physical fitness, for "better living through more vigorous health." Especially in the fields of physical restoration and preventive medicine, the social obligations of the medical profession are clear and the opportunity for national service is patent.

A Joint Physical Fitness Committee.—The immediate need is the formation of a functional joint committee of the American Medical Association and the National Council on Physical Fitness with strong and equal representation of the two organizations. This will furnish a broad based competent, professional leadership for a movement that will be immediately largely remedial in character but which from the beginning will be preventive in character and more so as the program evolves. The program should immediately seek Presidential and Congressional support to help in the improvement of physical fitness of the civilian population, to make it a part of the American consciousness and even of the American conscience by declaring the twelve months beginning with September 1944 a year of emphasis on physical fitness.

PHYSICAL FITNESS YEAR

The Proposal.—The National Committee on Physical Fitness specifically requested the cooperation of the American Medical Association (1) through a committee of five to act jointly with a similar group from the National Committee in the development and operation of a physical fitness special emphasis year; (2) the designation of a year beginning Sept. 1, 1944 as the "Physical Fitness Year" during which the Physical Fitness Program will be put into effect on a nationwide basis; (3) in the announcement by high authority (President or Congress) of the "Physical Fitness Year"; (4) to develop future planning during the Physical Fitness Year, which might include the consideration

of a suitable organization to handle the problem in perpetuity and to forestall for the future a recurrence of the situation such as herein revealed; such a permanent organization might well be one analogous to the National Research Council to function in the future in the realm of health and physical fitness as the National Academy of Science has functioned in science since created by Lincoln as a war measure in 1863, and (5) a National Physical Fitness Foundation might well merit and receive liberal private and public support.

A Broadly Based Continuing Program.—This would only initiate a program that will go on for years. It must become a part of our school programs at every level—elementary, secondary, advanced and adult. It must become a part of the personal hygiene and regimen of each individual as expressed in habit. It must find continuing expression in school journals, medical journals and journals of general circulation. There must go on comprehensive programs of research under the direction of the Joint Committee on Physical Fitness as well as stimulation of research in the university graduate schools and institutes of research, in insurance companies and in industrial personnel departments. The coordination of this research which is essential for the long time program will be done by the Joint Committee or by a special agency created by it, the Foundation of Physical Fitness.

I have only sketched and suggested the obvious need and the great opportunity which is before us for making the nation biologically fit for whatever is its mission in the postwar world. It is essential for our development as a nation. By making us more fit it will make us more dynamic. It will make us ready for the great opportunities ahead of us. In such a program in the interest of the whole nation for generations to come the medical profession will join with parents, educators, social workers, public health leaders and others. The special knowledge of the medical profession, its accepted leadership in the field, its social vision and its strategic social position will be an essential in a continuing long time program for a stronger, a greater America.

ABSTRACT OF DISCUSSION

DR. RAYMOND W. WAGGONER, Ann Arbor, Mich.: The medical survey program, which was announced last October and has been functioning since that time, consists primarily in getting information to the induction station through the use of certain forms. Form 210 is a form used to designate the individual, provided he has been in some mental hospital or has received treatment for mental disease by his physician. This is cleared through agencies and hospitals and through the social exchanges. Form 212 is a medical-social history form and has to do with the social and medical adjustment of the individual up to the time he reaches the induction station, and that is filled out by a specially designated agent called the medical field agent. One or more of these individuals, who should have social service training, is attached to each local board. There are more than 9,000 of them in the country at the present time. Forms 213 and 214 contain information obtained from the schools, and these are filled out by teachers in the school system. This information is in compact form and can be used by the psychiatrist at the induction station in a short time. It makes possible the rejection of men who might otherwise be accepted and who might fail in the military service, and it also makes possible the rejection of some men who might otherwise be rejected at the induction station and who might be capable of serving. Thus it makes for a more efficient screening program from the

psychiatric standpoint. More physicians must be made aware of this problem. More general practitioners and more non-psychiatric specialists must become grounded in the basic psychiatric precepts and simple treatment procedures so that minor neuropsychiatric problems can be handled by them without referral to a neuropsychiatrist. This I think can be brought about first by a better understanding by the medical profession of the immensity of the problem and secondly by establishing a better basic training method. It seems to me that the medical schools should and must establish a better psychiatric training program. Teaching hospitals must do more than they are doing at the present time in training interns and residents in psychiatric precepts while they are being trained for service in other specialties.

MAJOR GEN. GEORGE LULL: During the past few years I have discussed privately with Colonel Rowntree some of these problems. It was hard for us to realize the exact state of the youth of the nation as revealed by statistics from the draft notwithstanding the fact that we had statistics from the draft in World War I, which were bad enough. These figures have been improved in certain aspects and are relatively worse in others, especially in the emotional group of diseases. It was planned to have some of these defects corrected by the profession at large without any organized effort. This was a failure. When we started out we wanted a physically fit army, an army made up of young men who had practically no defects. We gradually lowered our standards. We had to if we were to get an army. We had to take cases of venereal disease and treat them. We had to take the hernias and operate. We had to take the dental defects and correct them, and the amount of dental decay and other dental defects was appalling. The Dental Corps gives some interesting statistics: I think the best one that I have heard is to the effect that if all the soldiers who had partial or complete dentures made were put together they would comprise fifteen infantry divisions. This does not include, of course, the ordinary men who had fillings or extractions. That has been a big problem for the Dental Corps and in many of our camps they have worked three shifts of eight hours each. It is all right for the Dental Corps to work three shifts of eight hours each, but it has encountered serious difficulties as to what man would come around at 3 o'clock in the morning to have a tooth pulled after he had drilled all day the day before. So that there have been certain administrative difficulties. At one post in the Army I know that at the present time they are doing ten herniotomies a day. At this station a number of small units pass through for certain phases of their training, so that their pool is being replenished all the time by men with hernias and with certain other defects. Colonel Rowntree has told you about the large group of individuals who have remedial defects and whose defects are to be corrected. There is another group which is probably more serious than this, and this group is made up of those who have defects which could have been prevented earlier in life. It is too late now to do anything about this group, but I believe that we, as representatives of organized medicine, will have to take a stand and render medical guidance to any plan that is put into effect in this country to improve physical fitness. Every man in the medical profession will have to assist in this physical fitness program. The physical fitness of our youth is not improving on the whole. It is probably worse than it was in the last war. There are many factors other than the medical ones which have a bearing on this physical fitness, but something has to be done about it and I think that we are approaching it in the proper manner at the present time. It means that every man must do his part.

DR. R. L. SENSENICH, South Bend, Ind.: Within recent times there have been an increasing number of proposals from labor unions to the Council on Industrial Health of the American Medical Association expressing a desire not only for preemployment examinations but also some periodic health examinations and educational work in health matters. Now a new problem has arisen by reason of the fact that there

will be so many men returning from the military services who must have thoroughgoing physical examinations and placement on a basis of their ability to do a particular job if they are to be given their old positions in industry and are given any priority in that respect. This problem also has come to the Board of Trustees, and while we were familiar with this activity in a national way it seemed to lack as yet real form, definition or any real proposal as to the mechanism to be followed. The definition of physical fitness as it has been presented to the Board is that fitness, first, will result in a minimum of disability due to sickness of any type; second, will result in ability to recover rapidly from fatigue and exhaustion. Industry is interested in that. A fitness that will insure the ability to perform any task, whether military or civilian, efficiently within the limits of the human body. Physical fitness based on an ideal which will demand a common effort on the part of the individual to maintain vigor and health, and along with that will have some stimulation to appearance and those things which should be, especially to growing youngsters, of some pride in endurance and ability to do the thing which we stimulate in athletics in the schools today. Fitness based on sound home, school and community training. This definition includes the factor which we have all come to realize has been more or less missing; that is, some education in self discipline. The Trustees, after giving thought to this whole matter, appointed a committee of five to participate with a committee of equal number from a group of the National Council on Physical Fitness. As I understand it, these two groups are to be advisers to the activity. The Council itself comprises a much larger number of many agencies in order to give it breadth of interest and means of activity, but these two groups are presumed to advise and are given assurance that their advice will be given consideration, which is of some importance in so large a group. The committee appointed by the American Medical Association is composed of General Lull, Dr. L. A. Buie, Dr. Morris Fishbein, Dr. W. B. Stroud and myself. This is a big program. It is going to take a long time after its public announcement to accomplish its purposes.

DR. WALTER FREEMAN, Washington, D. C.: The importance of physical fitness as stressed by Colonel Rowntree is well founded. It has to be built up after the war. We are soft. At least we have been. I hope we are getting a little tougher now. The program that is to be set up is undoubtedly manifold, but essentially it is based on the combination of facilities, time and leadership. Facilities for this recreational-toughening-program have to be supplied by the communities. The time necessary for this restitution of the physical and mental stability has to be forthcoming, and probably the employers will find it to their advantage to grant some time during the working period for this program of activity. The utilization of time and the utilization of facilities will depend on leadership.

DR. HERBERT F. ROBB, Belleville, Mich.: The recognition of our physical defects is one thing and the cure of these defects is another. One is simple and the other is complex. The cure of those problems and their prevention take into consideration not only heredity but the environment—and the rapidly changing environment—and variable reactions of the individuals to those environments. The American nation has gone through one of the most rapid revolutions of any environment of any nation in the history of man; that is, the revolution from an agricultural frontier civilization over to an industrial, urbanized civilization. The strain of urbanization is intense. In making Selective Service examinations in the southwest corner of Wayne County, Mich., I have had people from every foreign nation and every section of the United States. Those who were mentally and physically unfit were largely the product of broken homes which were in conflict with civilization and the teachings of organized religious and political groups. If we will consider the psychosomatic problem of the individual we will arrive at a better solution of our problem.

PHYSICAL FITNESS PROGRAM

A REPORT OF MEDICAL AND DENTAL EXAMINATIONS OF 5,620 SENIOR AND JUNIOR HIGH SCHOOL STUDENTS

CARL A. WILZBACH, M.D.
Commissioner of Health
CINCINNATI

Even in matters as vital as health it would seem that it takes a war to do a job that could have been done well years ago. It has always been difficult to have acceptable school health examinations made and harder still to have the defects found corrected. The task of getting these defects corrected is usually left to the school physicians and nurses. In time of war, however, with every one wanting to do "his bit," latent ability and help can be called on both to make the examinations and to assist with the efforts of having corrections made.

When the United States Office of Education proposed the High School Victory Corps Physical Fitness Program in January 1943, Cincinnati joined with other cities in the nation and put into effect this war emergency program. It was pointed out at that time that there were 28,000 high schools and 6½ million high school students. It was further stated that there was a war to be won and that the high school students are a potential source of trained manpower and that they should prepare youth for war service and for active participation in industrial, agricultural and other war efforts. Preinduction courses given the boys and girls included guidance in war service, community services related to the war and finally a course in physical fitness.

Before entry on the physical fitness program a health examination was required. The task of examining more than 5,000 students required considerable organization. The school medical services in Cincinnati are a function of the health department. Conferences for discussing organization and plans were held. These included the superintendents of schools, the commissioner of health, the director of school hygiene, the director of physical education and the director of dental hygiene. The examinations were made much as they are in large induction centers for selectees and were done in each school. The examination forms used were similar to those prepared for Army officers. Eighteen physicians and forty-three public health nurses and supervisors employed by the health department were responsible for the physical examinations. Dental examinations were made by dental hygienists. The extra assistance made possible because of the war stimulus was given by Red Cross volunteers, nurse's aides, parent-teacher representatives, school principals, physical education teachers, classroom teachers and the women's auxiliary of the county medical society.

Previous to the health examinations, auditorium lectures were given explaining the reason for the examinations and the necessity for hearing tests, blood tests, x-ray examinations of the chest and other parts of the examination. The need for having defects promptly

cared for was also stressed. In addition, a special preinduction course on health education, running through the entire school year, was inaugurated.

The organization for the correction of defects was augmented by the school personnel. A student needing medical or dental attention was first approached by the school nurse and then, if necessary, in succession by the classroom teacher, the physical education teacher and the principal. Each of these were provided with a list of the students requiring attention. Needless to say it was these added obligations taken on willingly because of the war emergency by the school teaching force that helped to make the efforts successful.

While the number of certain defects found was small, it must be remembered that those examined were junior and senior high school pupils. Besides having had the care of private physicians, most of them had been examined in preschool round-ups and in schools in the first, third, fifth and ninth grades, and after that some of these students were examined a number of times to qualify for athletic competition. Almost all of the gross organic defects were already known to the school doctors, nurses and school authorities. Efforts had been made throughout the school life of the student to encourage him to secure the needed corrections. It is recognized that some defects could not be overcome, and they are included in the total figures. Records were kept on corrections until May 31, 1944. Since that time additions could be made to the corrections, and many other pupils preferred to wait until the summer vacation for their medical and dental attention.

Five thousand, six hundred and twenty white and Negro senior and junior high school boys and girls were examined. In this number 2,293 physical defects were found. Some students had more than one defect.

Four thousand, six hundred and ninety-eight students, 83.5 per cent of all examined, had one or more dental defects.

VISION

Reviewing the more important organic defects most affecting the future health of the student, it was found that 342, or 6.1 per cent, had impairment of vision. Some of these students had been fitted with glasses that at the time of examination did not correct their faulty vision; some had been to the ophthalmologist and had failed to return for recheck; some had glasses but were not wearing them. By June 1, 1944, 235 students had had their eyes corrected by physicians and 42 were under their physicians' care. Corrections amounted to 80 per cent.

HEARING

Individual hearing tests were made on 5,623 students using the Maico type D-18 audiometer. Of this number 217 were retested. A total of 116, or 2.1 per cent, had some hearing loss, and these were referred to their physicians. A special referral form was sent to the otolaryngologist suggesting that lip reading classes were available should he wish to recommend them. A large group of volunteer Red Cross nurse's aides, under the direction of registered nurses, made the hearing tests. Qualified otolaryngologists had cared for 69 of these 116 students at the completion of this report.

NOSE AND THROAT

Closely related to the hearing problems and with the possibility of causing serious organic disease were found 137 boys and girls with enlarged and diseased tonsils.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

Miss Florence Schrieber, R. N., supervisor of school nursing, organized and guided the entire program and made this report possible. She was ably assisted by health department physicians, nurses, technicians, laboratory specialists and particularly Dr. Bernard Schwartz, Dr. David Hensinkveld and a host of volunteers.

These defects made up 2.44 per cent of the total defects found. Here again the follow-up efforts to have tonsillectomies done are difficult, but a month before the school year ended 44 students had their tonsils out and 30 more had appointments with their physicians for operations.

TEETH

Of the 5,623 students examined dental caries was present one or more times in 4,698, or 83.3 per cent. These findings are similar to other surveys made, such as the National Youth Administration and the Selective Service examinations. It would seem advisable for the school dentists to come to some agreement with the dentists in private practice as to what is a cavity. In the efforts to have defects corrected the busy dentist in private practice did not always take kindly to the school dentists' referrals.

The importance of sound teeth has been emphasized in school dental programs. A check of the yearly school dental records in Cincinnati shows gratifying improvement. While the number of instances of caries found seems high, Dr. Horace Jones and his assistants reported most of the mouths examined in good condition.

HEART

There is no more important function of the school health service than to find abnormal and damaged hearts and to guard against further injury to the individual either in school activities or in after life.

In the initial examinations the school physicians screened out 242 students with some abnormal heart condition. Following the x-ray examination of the chest 61 were added, making a total of 303, or 5.3 per cent, of the total pupils examined.

Dr. Bernard Schwartz, cardiologist and director of the Max Stern Heart Station, with the help of an enthusiastic group of volunteers from the Woman's Auxiliary to the Cincinnati Academy of Medicine (which is the Hamilton County Medical Society), assisted by public health nurses, reexamined all of these suspected heart cases. Electrocardiograms, sedimentation rates, blood counts, basal metabolism tests and additional x-ray examinations were made.

On reexamination of the 303 with abnormal hearts, 209 were found to have no organic heart disease but included functional and accidental murmurs and neurocirculatory asthenia.

The remaining 94 had definite organic heart disease and of these 29, or 31 per cent, had rheumatic heart disease. There was an additional 16 per cent with possible rheumatic hearts. These gave a history of previous illness, and the examinations revealed suggestive signs and symptoms, all indications that they had rheumatic fever. Rheumatic heart disease then accounted for possibly 48 per cent of the total number of hearts with organic defects.

The examinations revealed 4 students with definite rheumatic heart disease with histories of previous attacks who at the time of their examinations had mild fever and should have been in bed.

In an effort to make the general practitioners conscious of rheumatic fever, in March of 1942 the Cincinnati Academy of Medicine and the Cincinnati Heart Council requested the board of health to make rheumatic heart disease a reportable disease. This request was promptly complied with.

Rheumatic heart disease is the most common form of heart disease in children and is said to be responsible for more deaths in ages 5 to 14 years than any other serious infectious disease of childhood.¹ It is further said that the toll of disability is far greater than that taken by poliomyelitis, for 60 per cent or more of rheumatic fever patients develop permanent heart disease.

Following the examinations, a letter including the diagnosis was written to the family doctor and signed by the cardiologist. This letter was sealed and carried by the school public health nurse into the home of the student.

TABLE 1.—Report of Heart Examinations

Total number with heart abnormalities found in screening examinations.....	203	or 3.38%
Reexaminations:

Where necessary these students were recommended for special vocational training suitable to the heart condition. Efforts were made to have them take classes with other normal pupils and to have the classes on one floor.

TUBERCULOSIS

It would seem that the high school is not the place to find tuberculosis; at least this seems true in Cincinnati. Three thousand, six hundred and twenty-two students voluntarily took x-ray examinations with 4 by 10 inch films. All questionable films were rechecked with standard 14 by 17 stereo films. One white male and 1 Negro female, or 0.05 per cent, were found to have active tuberculosis. This is all the more astounding when it is remembered that among this group taking x-ray examinations there were 368 Negro boys and girls. The tuberculosis picture is apparently changing,

1. Vital Statistics of the United States, 1940.

for until recently the 16 to 20 year old age level had one of the highest tuberculosis rates. Four suspected cases are being rechecked. From the x-ray findings, 82.5 per cent showed primary phase tuberculosis: 70.1 grade 1, 10.2 grade 2 and 2.26 grade 3. Of the 3,622 x-rayed, 626, or 17.28 per cent, had negative x-ray findings.

The x-ray diagnoses were made by Dr. David Heu-sinkveld at the health center of the Cincinnati Health Department.

SEROLOGIC TESTS

Serologic tests were made on 3,581 students, including 3,180 white and 401 Negro boys and girls. Twelve positive serologic reactions, or 0.33 per cent of the total, were found. Of the positive serologic reactions 9, or 2.2 per cent, were in Negroes and less than a tenth of 1 per cent (0.09 per cent) were in white children. None of the cases were infectious.

In studying the individual histories and reports of examinations, only 1 had a definite diagnosis of congenital syphilis. It was also difficult to obtain a history

or were under treatment by private physicians or public clinics.

Of the 4,698 pupils with dental defects, 2,540 were corrected by private dentists and an additional 535 were still going to the dentist. This represents 65.4 per cent of the total. Public dental clinics had corrected 144, and an additional 18 pupils were still visiting the dentist, accounting for 3.4 per cent of the total. Sixty-nine per cent had dental corrections or were under treatment by private dentists or public clinics.

SUMMARY

1. Five thousand, six hundred and twenty-three high school students were given medical, dental and psychiatric examinations as a part of the Victory Corps Program. Their general physical condition was excellent and a credit to the physical fitness program in the schools. Their good health status was further indicated by a low tuberculosis, venereal disease and organic disease rate.

2. There was found a need for more serious concern for rheumatic fever and heart disease in school children.

TABLE 2.—High School Physical Fitness Victory Corps Program Chest X-Ray Reports, Combined Term 1943-1944

of exposure or of past signs or symptoms. A diagnosis of early latent syphilis was made of 5 students. One student had had five years of treatment. All but one of these students are under treatment.

PSYCHIATRIC QUESTIONNAIRE

A psychiatric questionnaire, prepared by Dr. Jack Hertzman, acting director of school hygiene, was filled out by 4,213 students and 43 per cent recorded one or more significant symptoms. There were ten questions in all and they were asked in a manner that did not betray the purpose of the questions. The questions were related to the following: allergies, recorded 448 times, choking spells and pounding heart 341 times, stuttering 242 times, nightmares 225 times, dizzy spells and fainting 185 times, kidney trouble (bed wetting) 172 times, asocial tendencies 103 times, excitement over school examinations 92 times, pains and diet 55 times and fits 25 times. These investigations and findings will be reported on in detail later, and no attempt is made to interpret them in this paper.

A report on corrections shows that of the 2,293 physical defects found 801 had been corrected and an additional 491 were under treatment by private physicians. This represents 56.1 per cent of the total. Public clinics had corrected 359 and an additional 200 were undergoing treatment, accounting for 24.3 per cent of the total. Eighty per cent plus had physical corrections

3. Army induction doctors report these young men in good condition when they appear for examination, some with hernias repaired, others with minor surgery and dental needs cared for as a result of the school examinations.

4. There was a high percentage of corrections, due largely to volunteer assistance and additional help from school principals and teachers. These gains must not be lost after the war.

ABSTRACT OF DISCUSSION

COL. L. G. ROWNTREE, Washington, D. C.: This is prehabilitation at its best; it is a magnificent accomplishment. This is really what we advocated in prehabilitation three years ago. In Selective Service we hoped that some such program could be started. Startling was a 25.3 per cent rejection rate at 18 to 19 and a 45 per cent rejection rate for the Negro. There is a tremendous need in the Negro as compared with the white race. If we can multiply the results reported for Cincinnati by a hundred and apply this to the nation as a whole, a tremendous step forward will be taken that would mean much in the health movement among the youth of the nation.

DR. R. B. CRAIN, Rochester, N. Y.: I was much interested in what Dr. Wilzbach said about the percentage of heart cases found in his survey. Five and three-tenths per cent seems to me rather large, as it is generally considered, I believe, that between 1 and 2 per cent of school children have organic heart disease. Perhaps the additional x-raying and taking of electrocardiograms may have accounted for that higher percentage.

I was interested that out of the number examined he found a large percentage of rheumatic heart disease. This is in keeping with an experience which the Heart Committee of the Monroe County Medical Society had in Rochester about ten years ago. For four years we examined those students in high schools found in the annual inspection to have some cardiac abnormality, and it was our experience that from 25 to 30 per cent of the total examinees had organic heart disease. I believe our committee was able to free many of these students for normal activities in high school—participation in gymnasium and sports. After consultation with the family physician we were often able to persuade them to give these students more liberty. It is important that students are not continued as cardiac cripples through life through fear of injuring themselves by participation in normal sports. I should like to ask whether in the examination he described the family physician was consulted and greater freedom obtained for those who did not have organic heart disease.

DR. EMERY R. HAYHURST, Columbus, Ohio: I should like to ask Dr. Wilzbach in the follow-up procedures whether an inquiry is made about the nutritional status of these students. What is the fluorine content in general of the Cincinnati water supply, and did they note any correlations that might have a relationship to this high dental caries situation? Is the dental examination apparently limited to the finding of caries meant to include the gums? I have in mind, of course, the possibility of gingivitis without caries.

DR. A. A. PETER, New Haven, Conn.: What record system do you use for the continuation of observation of these thousands of children? Do you, for example, use Wetzel grade and record development on levels of correlation of age and height and nutritional status?

DR. F. L. RECTOR, Lansing, Mich.: I am interested to know what was found in relation to tumors, particularly cancer, in these youngsters. We have made some study of that problem in our work for the state health department in Michigan and have found that we do not have any figures on cancer morbidity; we have had a surprising number of deaths under the age of 20 from various types of malignancy. In compiling our cancer deaths under age 20 we have included leukemia. We recognize it is a form of cancer. It is universally recognized as cancer of the blood cell forming tissues.

DR. BERNARD A. SCHWARTZ, Cincinnati: Two things impressed me that I thought were important: 4 cases of rheumatic heart fever, which I thought an indictment of the general practitioner, not cases coming to the clinic but the white collar case being taken care of by the practitioner. The second point is hypertension. We found 14 cases of high school age students with definite hypertension who were sustained types, because these pressures were checked and rechecked. Mass surveys were made in Cincinnati from 1926 to 1936, giving estimates and percentages of cases of heart disease. The survey made this past year was refined and gave us much more evidence of what is going on in our public schools.

DR. CARL A. WILZBACH, Cincinnati: Only juniors and seniors were examined. There is an accumulation through the years. When you reach the senior year you have a collection through the years during which these youngsters were in school. Maybe that accounts for the higher percentage of cases of heart disease. On the rheumatic fever heart cases we tried to get a letter to the doctor of the child concerned, a sealed letter we hoped would go directly to the family doctor from the cardiologist. Not a great deal was done on nutrition. I think that is an important part of the examination, but it was not tabulated. I cannot give you the fluorine content of the water. Trained dental hygienists made the examination, and I am sure any unusual gum condition would have been reported. With regard to personal follow-up, I should say the children with defects remain on the lists of the school nurse as long as the defects are not corrected. A persistent effort is made to check back to find out if the defects are corrected. While the schools are in session nurse, the classroom teacher, the physical education teacher and the

principals all assist. We do not use Wetzel grade in our work. With regard to cancer, we did a rather thorough examination of the skin, and we have recorded those we found with acne and other skin diseases. We did not see anything that we thought was cancer.

PHYSICAL FITNESS IN INDUSTRY

W. P. JACOBS, LL.D.

CLINTON, S. C.

In this war emergency our leaders in Washington have called on the workers in American industry to make and keep themselves physically fit to assure their supreme contribution to the prosecution of the war. Selective Service figures show over one million men of the first two million called for military service rejected as unfit. This represents a serious problem and indicates the difficulty faced by our leaders in organizing an all out war.

Just as the military provides physical fitness training to make and keep the armed forces fit to fight, so must industry, labor and community provide opportunities for training for physical fitness to keep our working men and women in top condition on the home front. In the beginning, however, workers in the specialized fields have a perfect right to ask what specifically is meant by physical fitness? The terms are general and difficult of specific definition. Nevertheless, perhaps the following will suffice.

Physical fitness is a condition which results in a minimum of disability from sickness. It will insure performance of tasks efficiently and well. It will result in rapid recovery from fatigue and exhaustion. It will produce a high degree of health and vigor and a rugged endurance. It will facilitate strong self discipline, the avoidance of soft living, an increased pride in physical vigor; it will encourage self direction and inner determination.

The secret of physical fitness may be said to be adequate medical care, fresh air and sunshine, balanced relaxation, good food, proper sleep, regular exercise. This foundation involves a proper balance of the daily habits, sound eating, ample walking, daily calisthenics, care in exercise, participation in competitive sports most suited for the need of the individual. And above all else it involves patriotic determination to keep fit.

Physical fitness in industry, like other types of preventive treatments, has been slow in catching popular favor, and its growth has been unusually spotted over the United States. Education, while offering an assurance of very definite future dividends, has found the growth of its popularity very slow indeed. As a consequence only a relatively small proportion of the population has actually enjoyed the privilege of a higher education.

Physical fitness in industry involves extensive education to promote its expansion. In fact it is education of a very vital type. Its justification is sound and obvious and yet its adoption is slow and uncertain. The principal reason for this hesitation is that the advantages of physical fitness to industry involve too much of preachment, and the American people have learned the art of consigning most sermons to the other fellow.

Physicians can readily understand the psychology of the American mind, which surveys all prevention with

skepticism. The average American does not have too much confidence in his own consistency and therefore doubts his own ability to adopt the regular regimen or treatment necessary for prevention. He is much more inclined to let nature take its course and take his chances with the ultimate cure.

It is easy for any one to foresee that physical fitness in industry will increase production, reduce cost of production, improve individual productivity and earning power, assure greater happiness, longer life and better worker morale and perhaps afford a number of other plausible advantages. Yet in spite of the perfectly obvious benefits to be obtained by the workers and by management and stockholders as well, physical fitness is one of those creators of intangible profits the full value of which is not seen at a glance. With the modern industrial humanitarianism, however, the theme is growing in popularity and in value. The adoption of the principle in an industrial enterprise usually brings excellent results when it is planned, adopted and operated with and under the direction and advice of the medical profession.

Physical fitness as it applies to industry involves a highly technical analysis in application, and it produces its best results when undertaken under the influence of the medical profession. Nor is the application of the theme a group problem, as would be believed at the first glance. It is strictly an individual problem. It is the life of the individual which must be made more fit, and the formula required by each individual differs from the other. One man or woman can safely adopt one type of sport or other type of recreation for the building of physique, while another may find it necessary to select an entirely different method. Some can use very vigorous exercises, like baseball, basketball, tennis, football, boxing, weight lifting, hockey or other activities which demand unusual physical exertion, while others may find it necessary to confine their activities to horseshoe pitching, chess, victory gardening or just walking. The well rounded and soundly conducted program of physical fitness in industry must take all of these factors into consideration to be at its best and be based on the careful diagnosis of each individual worker by a competent physician if it is to be safely conducted and if it is to produce the best results.

Next to expert professional advice, the greatest essential of a successful physical fitness program is planning. The ordinary haphazard, hit and miss type of program can easily do more harm than good. There must be systematized planning if the program is to attain proper results, if it is to receive popular acclaim, if it is to earn adequate participation and if it is to avoid the dangers of indiscretions.

Planning involves a careful advanced analysis of the field, of the objectives sought, of the equipment available and possible, of the compelling recreational and athletic habits of the people whom the program is expected to aid. The survey should incorporate adjacent fields, their customs and environment.

It should differentiate between age and sex groups and the potentialities of participation by management, labor and the community. It should be a comprehensive study of all factors which handicap, help or otherwise influence the health and strength of the individual worker. A study of individual and community living habits is essential. A study of diets, a survey of the

clinical records covering the industrial community if available will greatly facilitate the analysis of the need of a physical fitness program and the results which may reasonably be expected. Likewise the study of sanitation and a study of the local supplies of food which can be contaminated is indicated. Drainage, garbage disposal, refrigeration and the many other factors which influence community health should be studied to determine whether there are apparent and glaring general conditions which are so flagrant as to jeopardize the health of the community.

However, the secret of the success of a program of industrial physical fitness is found not in the community services but in the education of each individual. Physical fitness is a very personal and individual problem. When and only when the individual is convinced that greater personal health and individual strength will pay him dividends both tangible and intangible can one reasonably expect appreciable results from such a program.

We have heard much talk of state or group medicine, and there is no denying that there is a great deal of glamour attached to such mass practices. However, the actual results of group medicine are disappointing except where the industry-wide effort is intended merely as a forerunner to and a stimulant for individual action. Physical fitness, like medicine, is an individual and very personal function. Its success hinges on the question of what the individual will do about making himself more physically fit. While industrial programs of recreation and sports are built around mass action, their success is measured by the physical condition of each individual, and that is dependent on the correct diagnosis of the need of each individual and the extent to which the individual embraces his or her opportunities to get and keep fit.

Americans, more and more, have quit the playing fields to sit in grandstands and stadiums. We have become a nation of spectators, thrilling to the feats of professionals, semiprofessionals and pseudo amateurs. We rent cushions to sit on at the games and stuff ourselves on peanuts, soda pop and hot dogs.

There is, of course, a place for the great sports spectacles, but there is an even greater need for individual participation in moderate and healthful exercise.

In the adoption of a physical fitness program, management and labor and the community have a responsibility to encourage and aid the individual to become and keep physically fit.

The aim of every program should be participation by all employees.

There should be widespread education as to the importance and the need of physical fitness. All community facilities should be made available. Programs, wherever possible, should be made self supporting and self directing. And, as America will never become enthusiastic about regimented calisthenics, the competitive spirit should be stressed and physical fitness programs built around individual participation and the "will to win" spirit. Leadership should be selected and developed from among the workers themselves. The full cooperation of all community agencies should be enlisted. All types of recreation and sports which lend themselves to the local situation should be utilized to make the program as broad in its coverage as is possible, and the program should be made an all year round effort.

The larger industries throughout the country are making rapid strides in this field. There is nothing

particularly new about it except the emergency in which we are living. From a long range standpoint, the further we go in our high tension type of modern living the more we need to emphasize concerted individual action and keep physically fit. But in the war emergency, when the success of our armed forces is depending so completely on the ability of our workers on the home front, physical fitness in industry becomes a compelling need and utterly indispensable.

The accomplishments so far in this field can be largely credited to the members of the medical profession who have been working so faithfully in preserving the health of the workers in the industries of America. The future success of physical fitness in industry will necessitate the combined capacity of the medical profession of America. It is a highly technical and highly specialized job which involves medicine, psychology, sports, physical education, community planning, leadership and in fact all phases of human life. The program of physical fitness in industry merely offers a vehicle through which the skilled services of the physicians of the country may be broadened in scope and in contribution, in an opportunity for the practical popularization of preventive medicine as well as curative. While the responsibility rests on the individual worker himself, Doctors of America the opportunity is yours.

Thus have I briefly outlined a nontechnical description of a well rounded physical fitness program. The success of this program, of course, depends on the full cooperation of all concerned. Though it is a matter of dealing with preventive medicine, I am not going to say that the full responsibility of the program devolves on the physicians; I am here, however, to pledge the full cooperation and inspired leadership of the agencies of the government designed to promote physical fitness in industries. I am here to pledge the cooperation of the industries of America in executing this program; and while I have no authority to speak for them, I am confident that the medical profession will have the full support of the workers of America and their unions. They are well represented on our committees and are cooperating beautifully in this effort.

Nevertheless, the program will succeed in direct ratio to the full cooperation of all interested: industry, labor, government, education, local communities and, more important than all others, the medical profession. You are needed to do the work of indoctrination, to advise good management in the building and operating of the program and to give professional advice to the industrial workers as they get and keep physically fit.

There will be many who will discourage the building of this program on the assumption that it is another one of those ideals that start well but soon peter out. This is true. It is also true that truth hurts on occasions when the levity of our leaders overlooks the importance of persistence and constancy in a program of this kind. The medical profession can lead, enthusiastically support and lend its professional services and thus encourage a continuous constructive effort. Though physicians do not have the time to assume the leadership of such a national movement, their full support is necessary nevertheless. Without it the program cannot succeed.

It is my firm conviction that if through your counsel and assistance we can build a physically fit America,

the step will result in vast benefit to the workers of America and to the medical profession as well. And so I say to you, the medical profession, we laymen in the private and business fields lay this responsibility on you, and we urge you to accept a full measure of the inspiration and action which your profession is so capable of producing.

ABSTRACT OF DISCUSSION

DR. W. A. SAWYER, Rochester, N. Y.: Those of us who have been in industry for a number of years know full well the need for such a program. We know it now especially when the manpower situation is at such a low ebb. The sort of workers that we have today are in great need of rehabilitation and reconditioning. Medicine in industry has practiced prevention or at least has preached prevention and tried to practice it from the beginning. We know that physical fitness makes for greater production, less absence and better health. There have been occasional efforts to develop programs of this character in some industries. Today in most of the larger industries you will find recreational clubs and athletic competitions of various character but little of a specific reconditioning or training for physical fitness. Among executives there have been programs of gymnastics and other physical conditioning processes. I know one industry in which a gymnasium was provided. The supervisors, the executives, were urged and implored to take advantage of it. A number of them did. In the rubber industry I know another instance in which that was done for a number of years, but I have known of no industry in which the program was continuous or which took hold in any large way. In communities where Y. M. C. A.'s, Y. W. C. A.'s and the like offer facilities to industrial workers they are even holding gymnasium classes for the night workers, programs during the day and also programs during the night for some of the shift workers. They have not been great successes, however. There is a lethargy and apathy and indifference to them. It needs some sort of crusading spirit, some sort of new leadership, to develop this idea.

COL. L. G. ROWNTREE, Washington, D. C.: Mr. Jacobs is doing one grand job right now. He is the spearhead of the physical fitness in industry in the nation, under the auspices of the National Committee on Physical Fitness. Mr. Jacobs has told us how it is possible to attain these objectives individually, as communities, and nationally. The problem is largely one of education. It calls for vigorous medical support and leadership. This program really would make of every physician and medical man a counselor as well as a physician, a counselor in physical fitness. That cannot be done without education within our own ranks, because few of us know much about training for physical fitness. Mr. Jacobs is dealing at the present time with sixty million workers. If they will heed and accept and if we heed and accept, then this nation and the individuals in this nation will benefit immeasurably.

DR. CARL A. WILZBACH, Cincinnati: I have had the distinction of being a worker in the physical education field as well as in medicine. It is heartening to hear this paper. The medical profession has never supported exercise and physical fitness as it should have. We have to have wars to demonstrate how much it is needed in industry as well as in school or wherever our people are. It is something that the person has to believe in and then want to do. The job isn't easy unless you have all of the influence bearing on the problem coming to the individual. The medical profession ought to get back of this physical fitness program. The statement that a man after 40 years of age ought not exercise at all is not good advice. Much of the work today in the armed forces or in civilian life is being done by older men who are in good shape physically. If men stop exercising after 40, a great deal of the world's work will not be done.

DR. KINGSLEY ROBERTS, New York: You do not practice health conservation on people; you practice it with them. If you do not lay accent on the educational side of the physical fitness program, no matter how it is backed, it will fail. One factor that has not been mentioned here is the necessity of drawing the worker himself into the program, whether he is organized or unorganized. Such a program must carry with it the urging by the medical profession of the formation of labor-management health and welfare committees which will interpret what the physician has to say in terms that the worker himself will understand and will believe in. The medical care that the worker gets outside of the influence of the industrial physician is as important as the care that he gets within the scope of the industrial physician's activities.

DR. IRVING GRAY, Brooklyn: In a discussion of physical fitness in industry the importance of health education should be stressed. In Brooklyn, through the efforts of Dr. Landes, department of health officer in the Fort Greene district, there has been developed the Fort Greene Health Center. Representatives of industry, organized labor, the county medical society and various public health agencies are all cooperating in bringing to the industrial workers a complete health program. Information as to the importance of physical fitness, proper nutrition and preventive medicine reaches large groups of industrial workers through this organization. The preemployment or preplacement physical examination is essential in determining the character and extent of the activities of an individual in any physical fitness program. The plan of physical fitness in industry should really be an extension of the program which is part of the training in the schools. Industrial relationships which will reduce to a minimum psychosomatic disturbances would greatly enhance the value of a physical fitness program.

DR. MORRIS RASKIN, Detroit: I am from the Health Institute of the United Automobile Workers Union. The UAW-CIO has a recreation department which is developing a physical fitness program. The major difficulty is the method of making the program available to the worker. It is not necessarily true that the worker who does not take advantage of recreational facilities is apathetic. It is difficult for one who works ten to twelve hours a day, on a six to seven day work week, frequently in atmospheres of poor ventilation, suffering symptoms of chest pain, cough or fatigue, to leave his work, travel a number of miles to a point of recreation and then travel home. Therefore, in developing a physical fitness program, recreation facilities should be established in localities convenient to the workers and made available to workers on all shifts. The recreation department has several programs for workers on the midnight shift, with dances in order that their wives may adjust their living habits to the husband's work schedule. These factors are sometimes neglected in the establishment of such programs. The interests and desires of the people are rarely considered in the development and execution of such programs. Other factors also must not be forgotten. The social security factors are important. The worker who is anxious and suffers anxieties because of lack of security is a poor candidate for a physical fitness program. The worker whose housing is inadequate will not be a fit worker, no matter what type of program is developed.

DR. R. B. CRAIN, Rochester, N. Y.: I want to emphasize the old story of the periodic physical examination. In these times of stress and shortage of medical personnel it is not feasible to carry out this program of the annual physical examination, but I hope it will not be too long before that can be done again in many industries. The workers themselves are very anxious to know how they stand physically. It seems to me that any intelligent advice on physical fitness should be predicated on an individual physical examination. Physicians need to be better informed about correction of faulty health habits and poor posture. The physical educators have much to tell us. We have a number of loose ends in our physical examination that need taking up by some one trained to do it.

PHYSICAL FITNESS

ITS EVALUATION AND SIGNIFICANCE

J. ROSWELL GALLAGHER, M.D.

AND

LUCIEN BROUHA, M.D.

ANDOVER, MASS.

It has taken the impetus of war to bring home to us the great importance of physical fitness and to give that subject the attention it deserves: no one can be complacent when one realizes that 1 out of 4 of our 18-19 year old registrants fails to pass his Selective Service examination. But even now physical fitness is too frequently discussed in terms of only one of its various components, and many panaceas and programs are proposed which, although proper in themselves, are no more than single items in a well integrated and complete plan.

In this report three kinds of physical fitness are discussed: first, static or medical fitness, which is con-

TABLE 1.—A Condensation of Tables Published by Rowntree, McGill and Edwards¹ and Gallagher² Which Respectively Indicate the Percentage of Physical Defects Uncovered at the Selective Service Examination of 42,273 18-19 Year Old White Youths and at the Annual Initial Health Examination of 910 Preparatory School Boys.

Incidence of Defects Causing Rejection Among 18-19 Year Old White Registrants (42,273)		Incidence of Findings Among Preparatory School Boys (910)	
Defect	Per Cent Rejected	Finding	Per Cent
Eye diseases.....	1.9	Vision of 20/40 or less (un- corrected).....	1.9
Defective vision.....	2.6	Hypermetropia (uncor- rected).....	1.7
Eyes, all causes.....	4.7	Hearing loss of 20 decibels or more (all tones).....	1.7
Otitis media.....	1.1	Dental caries (far ad- vanced).....	15.1
Deafness.....	0.1	Tooth extraction advised.....	2.3
Ears, all causes.....	1.6	Rheumatic heart disease.....	0.7
Teeth, all causes.....	0.08	Hernia (inguinal).....	0.3
Nose and throat (all causes).....	0.31	Undescended testes.....	0.5
Tuberculosis.....	0.66	Personality disorder.....	2.5
Rheumatic heart disease.....	0.31	Speech defect (stuttering).....	1.6
	1.95	Diabetes.....	0.2
	1.59	Musculoskeletal (miscel- laneous).....	0.8
Mental diseases (all).....	2.72	Underweight (extreme).....	5.9
Psychoneurotic disorders.....	1.51		
Musculoskeletal (all).....	2.2		

cerned with the soundness of the organs of the body; second, functional or dynamic fitness, which has to do with the efficiency of the body in strenuous work; and, third, motor skills fitness, which is related to muscle coordination and strength in performing specific activities. A discussion of these three types of fitness is important, not alone for describing methods and results of testing them and indicating which procedures and programs may be of value in improving the level of man's fitness, but also for emphasizing that a many sided attack is essential. Fitness cannot be evaluated by means of a conventional medical examination alone: the latter appraises the quality of the organism at rest, can separate the sick from the healthy and segregate those having organic defects from those without them but does not reveal functional capacity. In short, such an examination does not provide a complete answer to the question of the examinee's condition and does not classify normal, healthy individuals into various groups according to their physical efficiency.

It is, in a way, unfortunate that this report is limited to physical fitness alone, for obviously the estimation,

From the Department of Health, Phillips Academy, Andover, Mass. (Dr. Gallagher). The Grant Study, Hygiene Department, Harvard University (Dr. Brouha).

maintenance and improvement of both the mental hygiene and the intellectual level of the population are of equal importance. The number of emotionally unfit uncovered by the Selective Service, the number of intelligent but untrained men noted during the course of their military careers, and the fact that almost half of those of our troops sent back to civil life are discharged for some neuropsychiatric disorder are clear indications of the magnitude and importance of this side of the fitness problem. Complete programs should be developed, including facilities for the prevention and correction of physical and mental disorders, for the determination of special skills and aptitudes and for appropriate educational opportunities.

MEDICAL FITNESS

Medical fitness, which is estimated by the conventional examination, must be considered first because it is fundamental. Rowntree, McGill and Edwards¹ describe the causes for rejection from military service, and another report² discusses the findings at the annual health examination of preparatory school boys. Each of these reports indicates the desirability of carefully examining members of these age groups and emphasizes the large number of correctible defects to be uncovered among them. The second report also shows that such an examination is far from superfluous even though the majority of the subjects come from economically privileged levels.

In table 1 a brief abstract of certain findings listed in these reports is given. The criteria were not identical, and the percentages should not be compared; both, however, show the desirability of proper, careful examination of these age groups. Such findings make it clear that fitness programs which insist only on exercises and games will fail to decrease the number of rejectees from military service. This decrease will come, first, from the proper control of syphilis, tuberculosis and rheumatic fever; second, by widespread medical examinations leading to the early correction of orthopedic disorders, hernia, nose and throat conditions, dental and visual defects; third, by an increased use of mental hygiene principles, and, fourth, by a proper diet and a better understanding of the fundamental rules of physical hygiene. Emerson³ has demonstrated the value of weight gain during adolescence as an indicator of good health, and the possibility of improving health by attention to diet, observation of sensible health habits and avoidance of excessive tension.

Not merely in times of war are such health examinations essential; this truism is mentioned here because the relation between good health and efficient day by day work is so obvious that it is often disregarded. There is frequently failure to discriminate between a state of being well and a state of optimum health; too often it is felt that the increment between the two is not worth the time and effort involved. The importance of following the medical examination by the correction of any discovered defects cannot be too strongly emphasized: the efficiency of such examination should be judged, not by the percentage of defects found, but by the number of these defects subsequently corrected.

FUNCTIONAL OR DYNAMIC FITNESS

The ability of a medically fit individual to do strenuous work cannot be estimated while he is at rest or performing mild exercise. In order to evaluate his fitness for hard work he must do hard work. For example, as shown in table 2, the similarity between the cardiac response of two individuals to hopping 100 times disappears after strenuous exercise. Resting heart rates before exercise and those taken at three intervals after each boy hopped 100 times are similar, but after a more prolonged and more strenuous exercise the heart rates show considerable difference: R. W.'s heart rate decelerated rapidly, A. C.'s slowly. The more strenuous test demonstrated differences in functional capacity which the milder test failed to disclose. Similar results were found when comparing the performances of 100 young men walking on a treadmill at 3.5 miles per hour on a 8.6 per cent grade for fifteen minutes with their performances when running at 7 miles per hour, grade 8.6 per cent, up to five minutes. Although statistically the relationship between recovery from mild exercise and hard exercise is a positive one in this material with a Pearson coefficient of correlation of 0.53, it is not clinically practicable to predict the capacity for hard exercise from the reaction to a milder exercise.

TABLE 2.—A Comparison of the Heart Rates of Two Individuals Taken First After Hopping 100 Times and Then After Performing a More Strenuous Four Minute Exercise

	Heart Rates Before and After Hopping			
	Sitting	30-60 Seconds	60-90 Seconds	90-120 Seconds
A. C.	74	80	76	72
R. W.	72	76	63	63

	Heart Rates Before and After "Step Test"			
	Sitting	60-90 Seconds	120-150 Seconds	180-210 Seconds
A. C.	72	136	120	112
R. W.	72	80	76	70

It is seen that in order to test dynamic fitness, which we define as the capacity to perform strenuous exercise and recover from it, the test itself must be strenuous. Whether a treadmill, an ergometer bicycle or the more simple step test is used is not important as long as the exercise requires no special skill, utilizes the large muscle groups and gives the heart and lungs so much work to do that a "steady state" cannot be maintained. From tests involving work of this nature, a "recovery index" can be derived. This index is based on the principle that the rate at which the heart decelerates after strenuous exercise provides a means of estimating dynamic fitness.⁴ That this assumption is true is demonstrated by the improvement of the index from week to week during a period of training, by a reduction of the index after breaking training, under the stress of inadequate diet⁵ or after an acute illness, and by a subsequent gradual rise on resuming exercise or shift to a proper diet.

A simple procedure, the step test, is adequate for reasonably accurate estimation of the recovery index. Slight variations in technique have been devised to make the test suitable for high school boys,⁶ high school

girls,⁷ college men⁸ and college women.⁹ For men the test consists in stepping on and off a platform 20 inches high thirty times a minute for no longer than five minutes, a period shown by experience to be adequate for adults. Younger boys and girls exercise only four minutes on a lower platform. The heart rate is

TABLE 3.—*A Comparison of the Initial Heart Rates and Recovery Indexes, Showing the Lack of Relation Between Them*

	Initial Rate	Rate 63-90 Seconds	After Exercise (Step Test) 120-150 Seconds	160-210 Seconds	Recovery Index
E. H.	70	146	120	116	61

J. D. (after training)....	74	38	38	36	106

counted for thirty seconds one, two and three minutes after exercise has ceased, and the recovery index is calculated by dividing the number of seconds of exercise by the sum of these three heart rates. The recovery index¹ is the

$$\frac{\text{duration of exercise (in seconds)} \times 100}{2 \times \text{sum of pulse counts in recovery}}$$

The higher the score the more fit the individual. Tables have been prepared for the rapid calculation of scores; they also include average indexes for those unable to maintain the exercise for the required period.

It will be noted that, in calculating the recovery index, only the heart rates taken during the recuperation period are used: the initial heart rate, the one prior to exercise, need not be recorded since it does not have a significant relation to an individual's ability to perform strenuous work.¹⁰ For example, as can be seen in table 3, 2 individuals, E. H. and R. K., having an initial heart rate of 70 beats per minute, may well be in very different states of fitness; a subject (C. V.) whose resting pulse is as low as 56 may be in poorer condition and have a lower recovery index than one whose initial heart rate is considerably higher (D. S.); and a subject (J. D.) may improve his condition after training and attain a much higher recovery index without significant change in his initial pulse. The well known effect of apprehension on the heart rate and the consequent difficulty of obtaining a true value for the resting pulse furnish sufficient reason for omitting the initial pulse in testing dynamic fitness. A similar lack of relation has been found between basal pulse rate, systolic or diastolic blood pressure and the capacity to perform strenuous work.¹¹

In the course of studies which led to the development of the recovery index and the step test technic, numerous physiologic data were collected and other indexes were calculated.¹² For example, measurements of oxygen consumption and blood lactate levels are of interest and value but are not always practicable because

of the technical difficulties involved. On the other hand, the recovery index can be obtained easily and is sufficiently accurate for the purposes for which it has been proposed.

The importance of estimating dynamic fitness cannot be overemphasized: the recovery index indicates the individual's present capacity for strenuous work, is useful as a yardstick in measuring his improvement under training, can evaluate the efficiency of any body building or conditioning program¹³ and, in general, helps to answer the question "What condition am I in?" The necessity of improving one's functional capacity is occasionally deprecated, but better than average fitness is desirable, not alone because a rare maximum effort may then be more adequately handled and within a wider margin of safety, but also because the commonplace tasks can be performed with less strain: "qui peut le plus peut le moins." The higher the degree of fitness, the less will any effort displace the individual from his previous physiologic state; consequently the greater will be his reserve for the next job, the quicker his recuperation and the more remote the possibility of excessive fatigue. Therefore tests for estimating fitness should be part of every thorough health examination of young people and should be repeated during the course of a conditioning program in order to determine the reaction to the program.

Chart 1 shows a wide distribution of fitness scores both before and after a training period. There is a great variation in the state of fitness from individual

TABLE 4.—*The Distribution of Initial Step Test Scores on a Group of 523 14-18-Year Old Boys, Together with the Percentage of Individuals at Each Score Range Who, After an Eight Week Training Period, Had an Increase or Decrease in the Recovery Index*

Distribution of Initial Recovery Indexes	Number of Subjects	Percentage at Each Score Range Who Improved	Average Improvement in Recovery Index	Percentage at Each Score Range Whose Recovery Indexes Dropped	Average Drop in Recovery Index	Percentage Whose Change Did Not
20-24	0	0	0	0	0	0

to individual, and, no matter what training is given, these differences persist. When an unselected group is given a typical secondary school training program, results similar to those shown in table 4 are obtained. In this study a high percentage of those who had low initial recovery indexes had improved by the end of the training period, and the average improvement was

greatest for those whose initial scores were lowest. Conversely, several of those with high initial scores showed a decrease during the training period, and the average decrease was greatest for those whose initial scores were highest. These observations indicate that an average program will most improve the least fit

Chart 1.—Distribution of fitness (recovery) indexes of 523 preparatory school boys before and after an eight weeks conditioning period. The solid line represents the initial scores, the broken one those obtained following the training period.

and least benefit the most fit. In order to raise their indexes, those with good initial fitness require a more strenuous program such as is given college oarsmen or schoolboy lacrosse or soccer players. When a group carefully selected to include only those men capable of achieving a high degree of functional fitness is subjected to a strenuous training, all will improve, but not all will improve to the same extent (table 5). Such experiments show that each man undergoing an appropriate training program achieves what is for him a maximum efficiency, related to his physiologic endowment. All individuals, though "medically fit," vary in the quality of their organic constitution and in the level of their potential physiologic efficiency.

The recovery index is not a measure of skill or ability to perform certain specialized activities but is primarily an evaluation of the quality of cardiovascular responses to strenuous exercise. Only when cardiovascular efficiency is a factor in the performance of a given activity should one expect improvement in the one to be accompanied by increased ability in the other.

The recovery index usually deteriorates strikingly during infection; even a common cold can produce definite lowering (chart 2). Compare a runner (J. R.) whose index was determined weekly throughout the training period with a team mate (H. H.) whose training was interrupted by illness but whose physiologic capacities were such that he responded well to training and, week by week, became more efficient, reaching what was his maximum performance under these conditions. A third runner (R. P.) did not have his training interrupted by illness yet failed to respond satisfactorily. This failure of his index to rise significantly during a period of arduous training suggests that continuation might not be beneficial: it may well be that the quality of his cardiovascular system is such that its capacity to improve is limited.

On the basis of such experiments, it may be stated that the value of serial determinations of the recovery index during training cannot be overemphasized.

MOTOR SKILLS FITNESS

The third aspect of physical fitness deals with the individual's ability to perform certain acts requiring strength, coordination and skill. Cureton¹⁴ has recently described several such tests, emphasized the inadequacy of many present physical education and recreation programs and urged that more time and attention be spent in teaching youths to handle their bodies efficiently. If, however, one is merely giving a screening test designed to select the weak, poorly coordinated and unskilful, it is necessary to include only a few motor skills. Vaulting, jumping, climbing and swimming are useful and their proper performance demands a reasonable degree of strength, flexibility and coordination. A simple and easily administered motor skills test, based on these activities, has therefore been devised for high school boys. It consists of a vault over a bar of various heights, a standing vertical jump, a rope or pole climb, a standing broad jump, a swimming test calling for knowledge of four different strokes and the ability to cover 100 yards.¹⁵ "Push ups," "pull ups" and running were not included in the test because they are part of most body building programs.¹⁶

If one was to choose which of the motor skills tests is most important, swimming would undoubtedly be selected. Cureton¹⁴ states that 26.55 per cent of 2,557 freshmen entering the University of Illinois in 1942 could not swim at all, a much higher figure than that reported by Kiphuth,¹⁷ who found that of 4,163 freshmen admitted to Yale from 1936 to 1941 only 1.7 per cent did not know how to swim. In a preparatory school of 700 boys, 1.6 per cent were unable to swim; 3.7 per cent could not swim 100 yards.¹⁵

COMMENT

A body building program is desirable for every healthy individual because it assures adequate daily exercise and provides for the general development of all muscles: it gives supplementary attention to the chest and arms of the runner and soccer player, to

Chart 2.—Changes in the recovery indexes of three athletes at approximately weekly intervals during a short training period. The temporary deterioration of fitness due to a common cold is seen in two of these curves, and the variation in individual response to similar training is evident.

the legs and abdomen of the weight thrower and to the cardiovascular system of all. Well rounded training should recognize these assets of conditioning exercises

and also take into consideration the psychologic, recreational and physiologic values of athletics. From our discussion of functional fitness and motor skills it is obvious that a proper physical educational program requires more than calisthenics. Obstacle races, swimming and games such as soccer and lacrosse, which develop endurance and the competitive spirit, are highly desirable. Tennis, squash and handball, which develop coordination, have particular value because they can be continued after school days are over.

Although "a sound mind in a sound body" is a commonplace among educators, some school systems are still reluctant to provide either sufficient time or personnel for the development of adequate physical education programs. The relation between good fitness and efficient academic effort is not always appreciated by the educator, and too often the athletic coach seeks to develop outstanding skill in the few and neglects to improve the all around physical efficiency of many. Often also authorities are timid about strenuous exercise. It is granted that such exercise may be harmful if it is given without knowledge of the individual's medical fitness, and it may also be harmful if not properly graded, gradually increased and carefully supervised. While much can be accomplished from well planned daily exercise, a "thorough workout" once a week will of course result in sore muscles; on the other hand, if the exercise is mild and short, little benefit can be expected. Frequently strenuous exercise is regarded as harmful because an individual was over-tired after his initial experience with the exercise he needed: it is to be remembered, however, that fatigue,

from cultivating motor skills would seem obvious. Nevertheless, neither is receiving proper attention, for Rowntree¹⁸ quotes Colonel Bank as saying "Many young men are entering the Army today totally unprepared for military life. It takes weeks to bring them into physical condition necessary for military training. This means weeks of wasted time and effort which could be avoided if every young man now in high school would engage in physical activities." It must, however, be remembered that such activities cannot be beneficial unless the individual has been found medically fit and unless the program is planned to suit his needs. Physical exercise must be carefully supervised and methodically increased as efficiency grows.

GETTING PATIENTS OUT OF BED EARLY IN THE PUERPERIUM

MORRIS L. ROTSTEIN, M.D.

BALTIMORE

The exact medical regimen of the puerperium has varied from century to century and from one social class to another. Obstetricians of old had their patients lie flat on their backs for fifteen or more days before allowing them out of bed. Their great fear was uterine prolapse. Our present day obstetricians are still adhering to this mode of treatment in part, or in whole, with very few variations. With the current shortage of maternity beds at the Sinai Hospital in Baltimore we have increased our maternity bed turnover by resurrecting the custom of allowing patients out of bed early in the puerperium.

Percival Willughby, Gentleman, in his *Observations and Midwifery*, written in the 17th century states "I knew a lady that constantly did keep her bed a fortnight after delivery and Gaines Wolveridge, M.D., a late writer in midwifery, in his book, *Speculum Matricis* advised the women to keep their bed, 5 days at the least, after delivery. For he sayeth, I know 'tis usual for them to rise at the 3 days' end, but this, to be sure, the longer women contain themselves in their bed, the more secure they are from danger, and I know by experience that his sayings in this case be found very true."

Charles White¹ of Manchester, England, 1728-1813, challenged the practice of keeping patients in bed for a prolonged period after childbirth. In his treatise on the Arrest of Puerperal Fever he states "The patient should be allowed up within a few hours after delivery. The sooner the patient gets out of bed, the better, and this should not be deferred beyond the second or third day at the furthest." An opposite opinion was held by Robert Gooch,² who in 1820 was the professor of obstetrics at St. Bartholomew's Hospital in London. Gooch cautioned his obstetric students not to allow puerperal women out of bed before the 21st day. The following is a quotation from his book on midwifery: "For three weeks after delivery, the patient should be kept chiefly in the recumbent position, the consequence

sore muscles and breathlessness after exercise in a normal individual are eliminated by becoming accustomed to that exercise, not by avoiding it. Occasionally failure to make a proper response to an exercise program may come from an undetected pathologic condition, and such unexpected failure should always call for a repeated physical examination, which may reveal a condition precluding benefit from the program or perhaps even presaging harm if it should be continued or intensified.

The desirability of developing and maintaining good dynamic fitness and the other advantages to be derived

of setting up soon after delivery with the heavy uterus suspended in the flaccid abdomen will be a prolapsus of this organ."

Allowing patients up out of bed early in the puerperium has not enjoyed widespread adherence in the last several decades, for the public had been educated to think that early rising in the puerperium was prejudicial to health. Until recently, almost all doctors shared this belief without attempting to prove or disprove this point otherwise.

In London during the blitz of 1940-1941 the authorities were fearful of an increased rate of casualties among hospitalized patients. As a result, a great many patients were delivered in the home. However, owing to the absence of proper facilities in their homes, hundreds of patients still had to be delivered in the hospital. These patients were admitted when they were in active labor, delivered, allowed up about a day later and sent home on the second or third day post partum. Reports from abroad showed that no ill effects resulted from this mode of treatment and, in addition, more patients could be accommodated per bed.

Vara³ states that in the Women's Clinic in Helsingfors 4,447 women were allowed out of bed very soon after delivery. His findings were that the incidence of thrombosis was definitely less in these women than in the women who were permitted to remain in bed for the usual length of time after delivery or operation. Likewise there was an improvement in function of the bowels and bladder, and the period of convalescence was shortened.

The obstetric group of the Alameda County Hospitals in Oakland, Calif.,⁴ increased their bed turnover by allowing patients to be sent home early in their puerperium if there were no postpartum complications. In their series of 3,400 cases about one third were discharged on their fourth day, 30 per cent between their fourth and eighth day and about 35 per cent after the eighth day. Their criteria for discharge were no postpartum complications and adequate care in the home. After a careful study they found that no complications occurred that were directly due to early discharge of the patient from the hospital.

Because of the greatly increased number of patients in the obstetric clinic at the Sinai Hospital of Baltimore, with the resultant bed shortage, we decided to allow a series of patients up early in the puerperium to increase our bed turnover and note the various effects if any. One hundred and fifty patients who delivered vaginally were chosen at random and allowed up on their third or fourth day after delivery. Parity and type of delivery were not taken into consideration. However, no patient with toxemia, heart disease or other complication of pregnancy was included in this group. The group was made up of 65 primiparas and 85 multiparas, totaling 150, with 51 spontaneous, 85 low forceps, 8 mid forceps and 6 breech deliveries, with 117 episiotomies.

MODE OF TREATMENT

In this series no ill effects were noted. The patients when allowed up felt well and were able to walk about and take care of both themselves and some of the inbed patients, thus greatly assisting a war depleted nursing staff. When allowed home, which varied from the sixth to the eighth postpartum day, they felt

strong and were better equipped to go about their duties of taking care of themselves and their newborn infants. The postpartum routine of these patients was as follows:

ROUTINE

1. Immediately after delivery the patient was encouraged to move about in bed.
2. Ergonovine hydracrylate $\frac{1}{320}$ grain (0.2 mg.) was given to each patient every four hours for six doses.
3. The patient was catheterized every ten hours if unable to void, but no antiseptic solutions were instilled.
4. Routine perineal care was instituted, consisting of flushing the perineum with sterile water after micturition and defecation.
5. The patient was put on a full diet immediately.
6. Liquid petrolatum was given on the night of the third day.
7. Starting on the third day, each patient was made to lie on her abdomen for one hour.
8. A soap suds enema was given on the fourth morning.
9. On the morning of the third or fourth day, if the four hourly oral temperature had not been above 99.6 F. for the preceding twenty-four hours, the patient was allowed up in the chair for two hours and again for two hours in the afternoon. Forty-five patients, or 30 per cent, were first allowed up on the third postpartum day and 105, or 70 per cent, on the fourth postpartum day.
10. On the fifth postpartum morning each patient was allowed to walk about as she desired, and she continued to do so until the day of discharge from the hospital.
11. Starting on the fifth postpartum day each patient was put in the knee-chest position for twenty minutes. This procedure was carried out each day until discharge and prescribed for two weeks at home following discharge.

The only criterion used for allowing patients to be up on their third and fourth day post partum was an oral four hourly temperature of not over 99.6 F. for the preceding twenty-four hours. If their temperature was above 99.6 F. they were kept in bed until this requirement had been fulfilled.

It was of great interest to see these patients getting about more and more each day, and on their day of discharge they were able to get about as well as before delivery. Under this routine the patients did not show the usual postpartum weakness and were able to help the inbed patients and spend their spare time packing pads and various sundries for the maternity department.

RESULTS

Lochia.—Normally the lochia consists of blood stained fluid for the first three or four days, after which it becomes paler with each succeeding day until the twelfth or fourteenth day, when it is almost whitish.^{4a} In this series the lochia was sanguineous on the third postpartum day and tended to become serosanguineous by the sixth postpartum day. On the day of discharge, which varied from the sixth to the eighth day, the lochia in 60 per cent of the cases was almost serous with very little blood in it. Being up on the third or fourth postpartum day made the lochia a little more profuse, which would be expected, because by standing or sitting upright the flow of lochia is helped by gravity. This increased flow lasted for twenty-four to forty-eight hours and then rapidly subsided, and by the sixth postpartum day the lochial discharge was quite scanty and serous.

The Uterus.—At delivery the uterus is about 2 finger-breadths below the umbilicus and from this level involutes down to below the symphysis in about twelve to fifteen days. In this series, with the regimen as outlined, involution was notably accelerated. It was found that the uterus involuted from its original posi-

4a. Schumann, E. A.: *Textbook of Obstetrics*, Philadelphia, W. B. Saunders Company, 1936.

tion immediately after delivery to half way between the umbilicus and the symphysis by the end of the fourth day. By the end of the sixth day the fundus was about 2 fingerbreadths above the symphysis and at the end of the eighth day at the level of the symphysis.

Stander⁵ states that at the sixth week postpartum examination 41 per cent of patients examined have retroversions. In this series, uterine retroversions were remarkably decreased. We considered the midposition of the uterus as zero and every position posterior to the midposition as a retroversion. Of the 150 cases examined at the sixth week post partum, and some were examined at a more remote date, 33, or 22 per cent, showed a retroversion and in 117, or 78 per cent, the uterus was in good position.

Bleeding.—As mentioned earlier, the initial bleeding was more profuse than usual on the patient's first day out of bed. Apart from this initial bleeding, no abnormal flow was noted. However, 3 cases of postpartum bleeding were encountered after the patient's discharge from the hospital. In 2 the bleeding occurred during the third week post partum. One responded very well to ergonovine therapy, while the other required dilation and curettage. The curettings showed some retained secundines. The third patient had profuse vaginal bleeding during the seventh week post partum which responded to ergonovine therapy.

Uterine Prolapse.—During pregnancy the uterus is supported by its ligaments, fascia, pelvic floor and abdominal wall in part. Following delivery, all these supports are lax and the possibility of uterine prolapse was regarded with grave concern when this series was started. However, getting patients out of bed on the third and fourth day of the puerperium did not produce prolapse of the uterus in any of the 150 patients. All were examined at the sixth week postpartum clinic and some at other periods more remote from the birth of the baby, and in none of these was uterine prolapse found. One of these patients has been subsequently admitted to the clinic with her third pregnancy, and on pelvic examination she was found to be approximately eight weeks pregnant. Her uterus at the time of examination showed no signs of prolapse of any degree.

Effect on Episiotomies.—One hundred and seventeen episiotomies were done in this series. They were either of the midline or mediolateral variety and chronic O catgut was used for the repair. Episiotomies were sutured in the usual manner, and 38 per cent of these were done by junior interns. Early rising post partum seemed to have no adverse effect on these episiotomy wounds. In pursuance of the thesis of getting patients out of bed on the third or fourth day of the puerperium, it was interesting to note that the patients with episiotomies were more comfortable when up and about than when lying in bed. They had a little discomfort on sitting up for the first time, but by the fifth or sixth postpartum day complaints regarding the perineal wound were few indeed. Two of the repairs showed skin separation. The remaining 115 healed by primary intention. At the time of the sixth week postpartum examination, all the episiotomy scars were well healed.

Morbidity.—This was not increased by allowing patients to get up early. In this series of 150, 9 patients had a morbid puerperium, giving a rate of 6 per cent,

which is well below the average morbidity rate of service cases (the Sinai Hospital morbidity is 7.5 per cent). Five of the elevations of temperature were due to urinary tract infections, urine cultures being positive for *Escherichia coli*. Three were due to a low grade endometritis and 1 to an upper respiratory infection. No cases of thrombophlebitis occurred in the series.

CONCLUSIONS

One hundred and fifty patients were allowed up on the third or fourth day post partum. The patients when allowed to get out of bed early feel much stronger and are better equipped to carry on their routine duties at home than those kept in bed the usual ten or twelve days. Involution of the uterus was accelerated and uterine prolapse was not encountered. Morbidity was not increased and the healing of episiotomy wounds was not affected by early rise post partum. No cases of thrombophlebitis occurred, and early postpartum activity lessens the hazard of such a complication occurring. It gives us a means whereby we can increase our turnover per bed in the maternity service.

THE EFFECT OF DIGITALIS ON THE CLOTTING MECHANISM

GEZA DE TAKATS, M.D.

R. A. TRUMP, B.S.

AND

N. C. GILBERT, M.D.

CHICAGO

It has always been a source of speculation why patients whose auricles have fibrillated for many years suddenly begin to throw emboli into the circulation. There must be some other factor than the presence of stasis. Stasis may exist indefinitely without thrombus formation, and there is no reason why stasis of itself should favor thrombus formation. It is known that superimposed infection is one factor in the production of multiple emboli. However, no attention has been paid in the past to a sudden change in the coagulation system of the blood, which in the presence of auricular stasis may lead to the formation of fresh thrombi. Some of these patients have received digitalis. It is our purpose in this communication to present data on the effect of digitalis on the clotting mechanism; animal experiments were employed to confirm the impressions gained by clinical observations.

While these studies were under way, two communications appeared which furnished experimental support to our contention that digitalis may favor thrombosis. Macht,¹ in a paper read before the June 1942 meeting of the American Medical Association, showed that digitalis shortened coagulation time both in-vitro and in the experimental animal. He also pointed out that heparinized animals were more resistant to digitalis poisoning than control ones. He concluded that digitaloid drugs had thromboplastic properties and thus antagonized heparin.

On a small but well controlled series of rabbits, Werch² found that when digifolin was given intra-

From the Laboratory of Surgical Research, St. Luke's Hospital, and the Department of Experimental Medicine, Northwestern University Medical School.

1. Macht, D. I.: Experimental Studies on Heparin and Its Influence on Toxicity of Digitaloids, Congo Red, Cobra Venom and Other Drugs, *Ann. Int. Med.* 18:772, 1943.

2. Werch, S. C.: Reduction of the Coagulation Time of Rabbit's Blood by Digitalis, *Quart. Bull. Northwestern Univ. M. School* 17:57, 1943.

venously to the rabbit in comparatively large amounts it caused a significant decrease in the coagulation time of the blood.

In a previous communication, one of us³ described a simple test of the clotting mechanism which consists of serial determinations of capillary coagulation time after the injection of 10 mg. of heparin. While the normal response remains quite constant in the same individuals, a number of factors have been and are being studied which inhibit or facilitate the response to heparin. It has been our experience that such a heparin tolerance is far more sensitive than single determinations of coagulation time and also more readily available for clinical use than the determination of prothrombin levels. In this study, while prothrombin levels were frequently determined, the response to heparin was used to observe the effect of digitalis on coagulation. To control the effect of dicumarol, prothrombin levels were determined by Smith's bedside test.

In some earlier work on dogs which had previously been vagectomized, it was observed that the usual dose of heparin did not prevent clotting and that the blood was kept from clotting only with much larger doses than were used in the nonvagectomized dogs. Even twice the usual dosage did not always prevent clotting in the cannulas. This neurogenic factor has received consideration in another communication.⁴

CLINICAL OBSERVATIONS

We first wish to present 4 case histories selected from a larger number which have left an impression on our minds. These histories are, of course, not conclusive but seemed suggestive enough to warrant further clinical and experimental investigations.

Chart 1 (case 1).—Prothrombin levels. The customary 600 mg. of dicumarol administered in diminishing dosage during the first three days resulted in a definite lowering of the prothrombin levels to 25 per cent of normal on the 5th day. A day previously the dose of dicumarol was cut to 50 mg. a day, which ordinarily will suffice to maintain the level between 70 and 80 per cent of normal. It has never been seen in our experience with this drug to permit a rise above 100 per cent of normal. This happened, however, coincidentally with the administration of 3 grains of digitalis daily; only another 400 mg. of dicumarol was capable of making an impression on the level of prothrombin.

CASE 1.—*History.*—Ruth T. S., aged 46, a housewife, was admitted to St. Luke's Hospital on June 10, 1941, thirty hours after a sudden occlusion of the left femoral artery. There was a previous history of rheumatic fever in childhood followed

by rheumatic mitral disease. The heart condition caused no symptoms until an auricular fibrillation developed. This did not return to normal with quinidine. The patient was placed on digitalis and was instructed in regard to its use. She regulated the dosage herself, varying this as indicated by the pulse rate and clinical symptoms. She did this successfully for three years, reporting occasionally for observation. She carried on her normal activities until June 1941 without symptoms. At that time she undertook an extensive trip which entailed a great deal of additional physical exertion. She became much fatigued and experienced some increased shortness of breath. To overcome this she increased her daily doses of digitalis. In a week severe pain in the left leg developed which necessitated her immediate return and her entrance into the hospital.

Examination.—On entrance the left lower extremity was cold and pulseless below the knee. The femoral artery was patent at the groin. A heat cradle was applied to the abdomen. Paravertebral block was done with 95 per cent alcohol to the first, second and third lumbar vertebrae on the left. This warmed up the foot, but the toes remained cold. Papaverine $\frac{1}{2}$ grain (0.032 Gm.) was given intravenously twice a day. She was discharged greatly improved. The digitalis dosage had been restored to the previous low maintenance level. She returned to her country home again with instructions in regard to regulating the dosage according to her needs.

Course.—The next admission occurred on July 7, 1941, when she experienced a hemiparesis after a slight increase in dosage of digitalis. Up until the time of the increased dosage she had been getting $1\frac{1}{2}$ grains (0.1 Gm.) of digitalis daily, together with 100 mg. of dicumarol, which failed to raise the coagulation time as expected (chart 1). Interestingly enough, at the onset of the hemiparesis the pain disappeared in the left lower extremity, in which she had experienced considerable ischemic pain from the previous embolus (chart 2).

CASE 2.—*History.*—Lilly M., aged 45, a housewife, entered St. Luke's Hospital on July 14, 1941 complaining of sudden excruciating pain in both legs, which had started five days previously in Greeley, Colo., at the altitude of 4,600 feet. This patient also had a rheumatic fever in childhood with a resulting mitral lesion and an auricular fibrillation. As in case 1, she had been taught how to use digitalis herself. She did this successfully over a period of years, except for a cerebral-vascular lesion seven years previous to entrance. At that time this was not considered to be connected with the digitalis dosage. Full recovery did not occur and there was some consequent disability. In spite of previous instructions in regard to altitude, she went on a trip to the Colorado mountains, where she experienced dyspnea even when at rest and peripheral edema developed. To overcome these symptoms she increased her digitalis dosage until a thrombosis developed, when digitalis was discontinued.

Examination.—On entrance the patient was in agonizing pain. There was irregularity of the pulse. Auricular fibrillation was present, with a rate of 126 at the apex and 110 at the wrist. The right leg was gangrenous to 3 inches below the knee; the left leg was cold, pale; the sole of the foot showed bluish discoloration. No pulse was palpable in either femoral artery. The diagnosis of old rheumatic heart disease with mitral stenosis and auricular fibrillation, and saddle-embolus of the aorta was made. A right mid thigh amputation was done within twenty-four hours.

Course.—In spite of paravertebral injections, heparin and intermittent venous hyperemia, gangrene progressed on the left side so that a mid thigh guifoline amputation had to be done on March 14, 1941, under sodium pentothal anesthesia. On Aug. 20, 1941 paraumbilical pain and vomiting occurred. Mesenteric embolism was suspected. The stump healed by

1 July 1941, after cerebral embolus
2 June 1942, no emboli since July 1941
3 February 1943, no more emboli

Chart 2 (case 1).—Three heparin tolerance curves, showing an improved clotting mechanism since the cerebral-vascular accident. The third curve shows a normal pattern, whereas the second is considered to be at the lower limit of normal.

3. de Takats, G.: Heparin Tolerance: A Test of the Clotting Mechanism, *Surg., Gynec. & Obst.* 77: 31 (July) 1943.

4. de Takats, G.: The Nervous Control of the Clotting Mechanism, *Arch. Surg.* 48: 105 (Feb) 1944.

primary intention. From August 20 on she had repeated attacks of convulsions. On September 19, with gradually failing heart, she died.

Autopsy.—This revealed chronic rheumatic heart disease, mitral stenosis, mural thrombus of the right auricular appendage, multiple infarcts of the lungs, spleen, left kidney and mesentery, saddle embolus to the aorta and focal softening of the cortex of the frontal lobe.

CASE 3.—History.—Margaret M., aged 53, a schoolteacher, entered St. Luke's Hospital on Dec. 7, 1941, three hours after the onset of motor and sensory paralysis followed by severe pain in both lower extremities. There was a history of rheumatic

Convalescence was uneventful. The left leg and foot became warm and pink, but the pedal pulses never reappeared. She was discharged two weeks after operation with well restored movement and sensation in both lower extremities.

Four months later an embolus occurred to the right femoral artery, and seven months later a saddle embolus of the aorta was diagnosed. Right femoral embolectomy was done during the second admission and another left femoral embolectomy was done during the third admission. While the second embolectomy was successful, the saddle embolus of the aorta put an irreversible strain on the previously crippled circulation and she lost both legs above the knee.

Autopsy.—The diagnosis of mitral heart disease, embolus to the bifurcation of the aorta and cerebral emboli was confirmed.

CASE 4.—History.—Leroy M., aged 42, an engineer, entered St. Luke's Hospital on May 16, 1942 with a cold, cyanotic, pregangrenous left leg. For the past six months there was pain on walking in both calves. A month before entrance he had suffered an acute coronary occlusion; he got out of bed against his doctor's advice on the second week and went back to work. Approximately three weeks after the onset of chest pain his left leg became numb and pulseless. Five days prior to the onset of the pain in the left leg he had begun to take 3 grains of digitalis daily because of a "rapid heart." The acute vascular occlusion in the leg was treated at home for ten days before entrance.

Examination.—On entrance the left femoral artery was pulseless at the groin; the entire extremity was mottled, purplish blue to 3 inches above the knee. The heart was enlarged

Chart 3 (case 4).—Heparin tolerance. The second curve was obtained after ten days, the patient receiving a daily injection of 0.6 Gm. of sodium tetrathionate.

fever at the age of 14 and again at 17. At the age of 21 "enlargement of the heart" was diagnosed and treated with digitalis and prolonged rest. Tonsillectomy was done at the age of 21. Hysterectomy was performed at the age of 37 for fibroids. Gastric hemorrhage occurred at the age of 39, originating from duodenal ulcer. Intermittent attacks of fatigue and ankle edema were treated with digitalis and rest; the exact dosage of digitalis was uncertain and irregular. Severe upper abdominal cramps occurred in the spring of 1941, diagnosed as gallbladder colic and verified by visualization. From Dec. 1 to Dec. 4, 1941 she increased the maintenance dose of digitalis to 3 grains (0.2 Gm.) because of extreme tiredness. On December 4 she developed severe abdominal pain, which was treated with morphine; this was followed by numbness and paresthesia in both lower extremities and a transient attack of blindness; on December 7 at 10 a. m. an embolism to the left femoral artery was diagnosed by Dr. Walter F. Hoeppner. Digitalis was given up to three hours before entrance.

Examination.—The patient was in extreme pain. The heart was enlarged to the left, with a mitral configuration. The auricles were fibrillating, with an apical rate of 150. The urine contained 1 to 10 red cells in several specimens. The left leg and foot were paralyzed, cold and pulseless. The right foot was pulseless, cold and numb but not paralyzed. The left femoral artery was pulseless at the groin; the right femoral artery was patent. Pedal pulses were absent on both sides. A diagnosis of left iliofemoral embolus was made; while intravenous papaverine and paravertebral block lessened the pain, the color and temperature of the extremity did not improve.

Operation and Result.—Six hours after the onset of symptoms, with retroperitoneal massage a large soft red thrombus was delivered through an arteriotomy of the left femoral. Good

Chart 4.—Heparin tolerance of Bertha B. a patient with no known cardiovascular disease. A, heparin tolerance was determined before and almost every day after the administration of 3 grains of digitalis and almost every day after the 5th day the response to heparin given daily. Note that up to the 5th day the response to heparin increased, possibly because of parasympathetic stimulation; on the 7th day, however, strong resistance to heparin was encountered; the figures indicate days after the administration of heparin was stopped; the curves promptly show increased sensitivity, actually a rebound as digitalis is being slowly excreted.

flow of blood was established from the proximal and distal stumps. Heparin was started four hours after operation. Digitalis was stopped temporarily.

Chart 5.—Heparin tolerance of Tillie R. For the dosage of digitalis, see text. On the 6th and 7th days the curves become much flatter; again after the drug was stopped there appears a rebound.

to the left, the pulse rate was 120 and intermittently irregular, and the blood pressure was 120/82. There was a pericardial rub. The electrocardiogram showed a partial heart block with nonconducted beats, sagging ST segment in leads I-4, low QRS group in all leads and low T wave in all leads.

Operation and Result.—Two days after entrance, with the diagnosis of iliofemoral embolus of ten days' duration following a myocardial infarct, with the patient under spinal anesthesia and at the level of positive histamine flares, a circular amputation was done 6 inches below the groin. The artery was empty and nonsclerotic at this level. The vein contained a soft friable clot, which was aspirated. The stump was completely closed, and heparinization was begun four hours after operation. The patient had a rather stormy course marked by fever, restlessness and delirium. A pulmonary infarct was suspected but not proved. A cerebral embolus may have been responsible for the mental symptoms. The patient left the hospital in good condition on the twenty-second day. He died a year later, at home, of another coronary occlusion.

Studies of Clotting Mechanism.—Two heparin curves are available, one on entrance and one after a course of sodium tetrathionate injections. This drug corrected the initial heparin resistance (chart 3).

These cases are merely illustrative of a number of clinical histories in our files. There are obviously other factors operating in many of these cases and certainly we cannot say that digitalis alone was responsible for the formation of thrombi and emboli. Thus in case 4 the myocardial infarct alone is frequently responsible for the mobilization of the clot, but it is significant that this occurred five days after daily doses of 3 grains of

digitalis were begun. However, these case histories stimulated us to proceed to more clearcut clinical and experimental observations on the subject.

Thus we placed Bertha B., aged 55, who entered St. Luke's Hospital for observation, on 3 grains of digitalis, which was maintained for six days. Heparin tolerance

Chart 6—This patient entered the hospital with digitalis poisoning, the digitalis was stopped on entrance. A normal tolerance curve was obtained on the 7th day.

was determined daily before and daily after the onset of medication. After the seventh day the drug was stopped and the heparin tolerance was determined for another four days. On the left side of the graph (chart 4) is seen the control curve and subsequent curves which show an increased reactivity to heparin up to the fifth day, on which day the patient showed a characteristic curve for a hyperreactor.³ On the sixth day the curve flattened somewhat, whereas on the seventh pronounced resistance to heparin was encountered. This same tolerance curve is shown again on the right as a zero curve. The tolerance rose very fast, on the fourth day exhibiting again a sensitivity to heparin, possibly due to the parasympatheticomimetic action of digitalis.

In the case of Tillie R., who was placed on 3 grains of digitalis for one day, followed by daily doses of $1\frac{1}{2}$ grains (0.1 Gm.), the curves became flat on the 6th and 7th days (chart 5). On the 7th day the drug was stopped, and again we observe the rebound to heparin sensitivity between the 4th and 8th days after digitalis was discontinued.

Jesse J., aged 39, with rheumatic heart disease, was admitted to the hospital with digitalis poisoning; digitalis was stopped on entrance. In chart 6, 0 represents the day of entrance. The greatest resistance to heparin was encountered on the 2d day, at which time heparin failed to raise the capillary coagulation time at all. Then the curves improved and on the 7th day one encounters again a normal curve.

To 2 patients, 6 grains (0.4 Gm.) of digifoln was given intravenously, the tolerance curves being determined before and one and one-half hours after the administration of the drug (chart 7). Both curves are normal before the drug was given. In the case of Patrick M. the curve became entirely flat after digitalis; in the second case the response was subnormal, but the change still quite noticeable. There were no clinical symptoms of any note, certainly no vomiting or diuresis.

Effect of gr vi of digitalis given intravenously on heparin tolerance

Chart 7.—Tolerance curves before and after a single intravenous dose of digitalis. The total dose of the drug is small, dehydration can be excluded in these experiments. The effect of digitalis in increasing the clotting factors is striking in both experiments.

conditioned to the heparin tolerance curves, which were determined at frequent intervals. The dogs were finally brought into a basal state, where they jumped on the table and were absolutely quiet during the serial determinations of coagulation time. From 0.2 to 0.1 mg. of heparin per kilogram of body weight was injected intravenously and capillary coagulation

times were determined before and ten, twenty and thirty minutes after the injection of heparin. The shape of the curves (chart 8, top column) was very much like the ones obtained in the human being. Only slight daily variations were encountered. Homer received 3 cat units daily from May 28 to June 8, 2 cat units from June 8 to June 21 and 3 cat units from June 21 to July 2. It will be noted that the heparin response promptly decreased after the administration of digitalis and together with the weight loss. During the last few days of the dog's life the curve flattened out completely. The dog's weight dropped from 11.5 Kg. to 7.75 Kg. at death.

In the case of Whitie, after six tolerance curves with 0.1 mg. of heparin per kilogram of body weight 1 cat unit daily was sufficient to diminish the response to heparin; in fact, on March 20 the response to heparin disappeared entirely. This dog was given $1\frac{1}{2}$ cat units of digitalis for one month and then again 1 cat unit for nine days. Comparing the curves in the top column with those in the bottom, the decreased reactivity to heparin is striking (chart 9).

Chart 8—The effect of digitalis on the heparin tolerance of a normal dog. Curves were run almost daily, but only a few of them are shown. The heparin response promptly diminished after administration of digitalis was begun. The top row contains the control curves, the bottom row shows a complete heparin resistance. The animal died on July 2. Digitalis effect was obvious after the first 15 cat units.

In the case of Oscar, 3 cat units from May 28 to June 9, 1943 followed by 2 cat units from June 10 to June 12 resulted in a complete abolition of the response to heparin. The dog's weight dropped from 9.7 Kg. to 7.4 Kg. in twelve days, at which time, on June 9, 1943, heparin was ineffective in the dose employed (chart 10). In the next graph (chart 11) after seven tolerance curves 2 cat units were given daily from March 23 to April 20. The effect of this medication on the curves is unmistakable. Digitalis was discontinued and together with the weight curve the curves rose until a normal response was obtained. Next the dog was again placed on 2 cat units and later on 1 cat unit of digitalis, but simultaneously 0.1 Gm. of sodium tetrathionate was given intravenously. This medication seemed to afford some but not complete protection against the thromboplastic property of digitalis. On June 21 and June 24 the curves were quite flat after the ingestion of 42 cat units. However, with the daily dose of 1 cat unit the sulfur compound seemed to cope better.

In the case of Blackie (chart 12) we again managed to develop a striking resistance to heparin after not more than twelve days of a total of 24 cat units. Again after discontinuing digitalis the heparin tolerance returned to normal. On May 3, thirteen days after the drug had

been discontinued, the heparin curve was normal. Digitalis was started again, now together with sodium tetrathionate in daily doses of 2 cat units. As in the previous graph, the sulfur compound did not sufficiently protect the dog against 2 cat units daily, but when 1 cat

Chart 9.—The top curve represents control curves; the heparin tolerance curves flatten out very shortly after digitalis is administered. Compare the first row of curves with those of the third and fourth rows. Heparin is inactivated during digitalization.

unit was employed the tolerance curves returned to normal.

The animal experiments clearly indicate that the action of heparin is counteracted by digitalis and that by stopping the drug the reaction of the animal to heparin returns to normal. The graphs also show that sodium tetrathionate, a sulfur-containing compound, is capable of elevating such flattened curves. The effect of sulfur compounds on the clotting mechanism has been the subject of another communication⁵ and here we just wish to emphasize its favorable effect on the increased clotting tendency of dogs poisoned with digitalis.

COMMENT

While the case histories presented are only suggestive, the additional clinical observations and the animal experiments leave no doubt that digitalis affects the clotting mechanism. The fact that heparin is less effective

Chart 10.—A normal heparin tolerance is converted to a complete resistance to heparin. Note heparin curves on 6/9, 6/10 and 6/12.

in the presence of digitalis action must mean that somewhere in the coagulation system digitalis opposes heparin. We have no data as to the mechanism of this action. Digitalis may have thromboplastic properties; it may mobilize prothrombin from the liver or even increase thrombin or fibrinogen. As a poison it may interfere with the oxygen-carrying power of the blood.

5. de Takats, G.: The Effect of Sulfur Compounds on the Clotting Mechanism, *Surgery* 14: 661, 1943.

For practical purposes it seems obvious that, pushed beyond a certain point, it definitely favors thrombosis and embolism. It would seem desirable to watch the clotting mechanism from time to time in patients who require digitalis, and particularly in those whose auricles fibrillate, since here the factor of auricular stasis greatly adds to the hazard of thrombosis.

Elsewhere one of us⁵ has studied the effect of sulfur compounds on the clotting mechanism. It was found that intravenously administered sodium tetrathionate invariably increased heparin action, but no drug was found that could be given orally for the same purpose. In our animal experiments, sodium tetrathionate seemed to prevent the action of digitalis on heparin tolerance. This drug has proved to be very useful in controlling the activity of Buerger's disease and may possibly be used after any type of thromboembolic phenomena to decrease the incidence of recurrence.

The action of small doses of digitalis, when the drug is accumulating or being slowly eliminated from the body, is equally interesting. During such a phase the heparin tolerance is increased; patients show a sensitivity to heparin. Since the parasympathetic drugs

Chart 11.—This graph illustrates the effect of digitalis administration and its withdrawal on heparin tolerance. When digitalis was discontinued the tolerance curves returned to normal. Sodium tetrathionate effectively counteracted the action of 1 cat unit of digitalis; 2 cat units, however, flattened the curves in spite of sodium tetrathionate given daily. This dose of tetrathionate (0.1 Gm.) should probably be increased.

mecholy and neostigmine have such action⁴ it may be that this is an expression of the affinity of digitalis to the cholinergic nervous system. Such small stimulating doses may benefit the coagulation system of the patient.

Digitalis opposes not only the action of heparin but that of the other frequently used anticoagulant dicumarol. This is of practical significance, since doses of dicumarol that produce satisfactory levels of prothrombin are unable to do so during the administration of digitalis or another digitaloid, uginin. This is illustrated in chart 13 in a patient whom one of us saw with a femoral embolus in the presence of a rapid auricular fibrillation. We are indebted to Dr. George W. Parker of Peoria for the data shown in this graph. It will be noted that to the customary dose of dicumarol, namely 300 mg. the first day, 200 mg. the second day and 100 mg. the third day the prothrombin level responded with alacrity. When the prothrombin level fell to 35 per cent of normal a maintenance dose of 50 mg. a day was prescribed; this failed to hold the level. On September 25 1 unit and on the 20th 2 units of digitalis were given. It was necessary now to give 100 mg. of dicumarol daily to obtain another drop of the prothrombin level, but

both were thrashing about, the shark making repeated attacks. The injured man was lifted on deck within one minute of the initial attack. He was bleeding profusely from wounds of the left leg. A tourniquet was applied to the left thigh, emergency dressings were appropriately placed, and he was rushed to the local Naval hospital, where he arrived three hours later, exsanguinated and in shock.

Fig. 2.—Note gashes on left foot and arched pattern of lacerations, set B.

Following the administration of anti-shock measures, he was taken to the operating room, where the left popliteal artery was repaired, the popliteal vein was ligated and muscle groups were rapidly approximated. A tip of a tooth found beneath the muscles in the popliteal fossa was removed. The patient died in shock four hours after admission and seven hours after the injuries were received.

A complete autopsy, including examination of the head, was performed at the Board of Health Laboratory, Gorgas Hospital, eleven hours after death. There was evidence of exsanguination; some congestion and edema of the posterior portion of the lungs were present. The only other lesions of interest were the injuries which are shown in the accompanying illustrations. A half dozen series or sets of lacerations, arranged in arches, were present on the lower third of the left thigh, the left leg and the left foot. A set of lacerations involved the anteromesial aspect of the middle of the right leg, and there were irregular lacerations of the left hand and right great toe. A tooth pattern suggestive of two, three and four rows of teeth could be recognized in several of the series or sets of lacerations.

Set A (fig. 1), which consisted of twelve individual lacerations averaging 1.5 cm. in length, arranged in two rows, extended deeply into the left knee joint. The medial condyle of the

femur, especially the cartilaginous surface, was crushed. Wedged into niches in the condyle were fragments of teeth, the largest measuring 1 cm. in its greatest dimension and similar to the fragment illustrated in figures 1 and 3.

Set B (fig. 2) involved the posterior and lateral aspects of the lower third of the left thigh. When the sutures were removed, the lacerated skin, subcutaneous tissue and biceps femoris, semimembranosus and semitendinosus muscles fell away, exposing the popliteal fossa (figure 3). The torn popliteal artery had been adequately repaired. The vein had been severed, and both ends ligated. The tibial nerve just distal to its origin from the sciatic nerve was irregularly torn but not completely severed.

In figure 3 is shown the tip of a tooth as it was found by the surgeon at the time of operation. On the popliteal surface of the femur were several grooves and gashes, and it appeared likely that the tip of the tooth broke off after striking the femur in this area.

Sets C and D (fig. 1) extended through the soft parts to each tibia, which was nicked and grooved; several tiny, irregular fragments of teeth were found in the periosteal tissue.

IDENTIFICATION

The tips of two teeth, one removed from the popliteal fossa by the surgeon (fragment shown in figures 1 and 3), and one removed from the medial condyle of the left femur, were shown on Oct. 12, 1943 to Mr. John T. Nichols, curator of recent fishes, of the American Museum of Natural History, New York, who identified them as "tips of the teeth of a small so-called man-eater shark *Carcharodon carcharias*, and from a small individual of this species probably not more than 7 feet or so long." Dr. C. M. Breder Jr., curator of the New York Aquarium, concurred in the identification.

COMMENT

In 1929 Phalen¹ reported a case of unprovoked shark attack in which a native Panamanian youth was attacked while swimming off Taboga Island, which is about 35 miles from Rey Island. The shark, seen by several persons, tore a leg off the swimmer. The shark was caught two hours later, and the leg and a portion of the bathing suit were found within it

Fig. 3.—Note tip of tooth in left popliteal fossa, as found at time of operation.

Conclusive evidence is at hand, therefore, that sharks will attack human beings. A discussion of frequency of such attacks in various parts of the world and of the use of shark repellents is beyond the scope of this report.

A SUGGESTED THERAPY FOR THE PREVENTION OF
GRANULOCYTOPENIA INDUCED BY THIOUREAE. D. GOLDSMITH, PH.D.; ALBERT S. GORDON, PH.D.;
GRACE FINKELSTEIN, B.A., AND HARRY A. CHARIPPER, PH.D.
NEW YORK

The administration of thiourea and its derivatives and the sulfonamides to animals results in the development of a state of hypothyroidism.¹ These substances produce this effect by interfering with the synthesis of normal thyroid hormone.² Clinical studies have shown that thiourea and thiouracil are effective in the treatment of hyperthyroidism.³ The possibility of the occurrence of agranulocytosis in patients treated with these drugs has been indicated in the work of Astwood.⁴ The present work will demonstrate that a neutrophilic granulocytopenia also results from feeding thiourea to adult rats. Since the granulocytopenia produced in weanling rats fed sulfonamides has been corrected by liver,⁵ it was decided also to test the effects of solubilized liver⁶ on the thiourea-induced neutropenia.

Eighteen adult male rats weighing 200 to 240 Gm. were fed a standard laboratory ration containing 0.5 per cent thiourea for fifty-eight days. Six animals of another group were treated similarly but in addition received 5 per cent of solubilized liver incorporated in the ration. Seventeen animals served as untreated

expressed as a percentage. Hemoglobin determinations were made with a Fisher electrohemometer. Differential white cell counts were made from dried blood smears treated with Wright's stain.

It will be observed from the table that a significant diminution in the total white cell count occurs in the rat after approximately forty days on thiourea and is not intensified by continuation of treatment. The most striking hematologic change observed in the animals receiving thiourea ration is the pronounced neutrophilic granulocytopenia. This condition becomes progressively more severe with continued treatment. It is to be observed, however, that administration of the liver almost completely prevents the development of the neutropenia. Eosinophil and monocyte percentages are not affected by thiourea. No typical basophils were encountered in any of the normal or experimental animals. The data also indicate that the thiourea-induced anemia is not accentuated and does not respond to liver therapy. There is, moreover, practically no change in the hemoglobin concentrations and the reticulocyte percentages.

It would thus appear that the granulocytopenia induced by administration of either the sulfonamides⁵ or thiourea, as shown in the table, may be prevented by liver. A norite eluate fraction of liver has been found to alleviate the leukopenia in monkeys maintained on a synthetic diet⁷ and that induced

All figures represent mean values. Numbers in parentheses indicate range in values.

controls. Blood samples were taken from the tail of each animal at the three different times indicated in the accompanying table. Total erythrocyte and leukocyte counts were made in duplicate. Red cell counts were required to agree within ± 4 per cent, and white cell counts to within ± 10 per cent. Reticulocyte counts were made from wet smears of whole blood previously diluted with 2 per cent sodium citrate and stained with brilliant cresyl blue. One thousand erythrocytes were counted for each determination, and the reticulocytes

in rats by sulfaguanidine.⁸ Waisman and Elvehjem⁷ have proposed that folic acid is the active agent in this liver fraction. By using the crystalline material, Daft and Sebrell⁹ have demonstrated that the corrective factor is actually folic acid. In view of these findings, the use of folic acid or liver in the prevention and treatment of the granulocytopenia resulting from the administration of thiourea compounds in hyperthyroid patients is suggested.

SUMMARY

The feeding of thiourea to adult male rats results in the development of a definite neutrophilic granulocytopenia. Simultaneous administration of solubilized liver almost completely prevents this neutropenic state. On the basis of these findings and those of others¹⁰ the use of liver or folic acid in the prevention and in the treatment of the thiourea-induced granulocytopenia is suggested.¹¹

Dr. Goldsmith is also of the College of the City of New York. This investigation was supported by a grant from the Commonwealth Fund.

Council on Foods and Nutrition

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
GEORGE K. ANDERSON, M.D., Secretary.

NUTRITIONAL VALUE OF WHEAT GERM AND CORN GERM

Wheat germ has attracted attention in the field of nutrition for many years. Consideration was first given to the embryo or germ part of the wheat kernel when it was found to be much richer in vitamin B₁ than the rest of the seed. Wheat germ was recognized along with yeast and rice polishings as an important source of this vitamin for both isolation work and treatment of beriberi. With increased production of patent flour and improved methods of separating the germ from the bran and middlings, wheat germ became an important commercial product. It has been estimated that 75 million pounds of wheat germ could be produced each year in the United States and Canada. Because of the high fat content of the germ some difficulty has been experienced in preserving it, but this has been eliminated to some extent by more careful manufacturing and processing and in one case by removing the fat with the production of defatted wheat germ.

In 1927 Goldberger¹ gave careful consideration to the antipellagra value of wheat germ and found it to be a good source. After the discovery of vitamin E, wheat germ and wheat germ oil were used as sources of this vitamin. Alpha tocopherol was isolated from wheat germ oil in 1936.² More recently there has been much interest in the quality of the protein in the embryo from cereal grains. The true nutritional value of this product can best be established by tabulation of the amount of each of the essential nutrients present. Fortunately rather extensive studies have been made during the past two years but there are undoubtedly other biologic values which still have not been evaluated. The available data on wheat germ as well as corn germ will be summarized briefly.

Grewe and LeClerc³ reported the following values for nineteen samples analyzed in their laboratory:

Water	7.4-11.5 per cent
Protein	18.3-35.3 per cent
Ether extract	5.2-15.0 per cent
Ash	3.1-4.9 per cent
Crude fiber	1.6-3.5 per cent
Sugar, mostly sucrose	6.6-17.4 per cent
Other carbohydrates	19.2-53.0 per cent

Most of the additional figures found in the literature fall within these ranges. The type of wheat, its treatment before milling and the kind of milling process all influence the composition of the germ. The commercial germ obtained from soft wheat tends to be higher in nonsucrose carbohydrates than that obtained from hard wheats. Some samples may contain appreciable quantities of bran or flour, and the amount of these substances affects the composition, especially the B vitamin content. Commercial preparations intended for food are usually considerably purer than those used in animal feeding. In the case of defatted wheat germ the ether extract would be very low and therefore the percentage of protein and other water soluble ingredients would be increased.

Minerals.—Grewe and LeClerc reported the following average figures for the mineral content of composite samples of germ obtained from various classes of wheat: total ash 4.26 per cent, magnesium 0.32 per cent, calcium 0.055 per cent, potassium 0.93 per cent, phosphorus 1.05 per cent, manganese 0.020 per cent, copper 0.001 per cent, iron 0.0058 per cent, chlorine 0.082 per cent, sulfur 0.23 per cent. Zinc and aluminum are also present in minute amounts. Andrews and Bailey⁴ reported a total phosphorus content of 1.24 per cent with the following distribution: phytin phosphorus 47.9 per cent, lipid phosphorus 5.7 per cent and undetermined phosphorus 46.4 per cent of the total.

Protein.—Boas-Fixsen and Jackson⁵ and Chick and her associates⁶ found wheat embryo protein to be about equal to whole wheat and yellow maize proteins and slightly superior to the proteins of the wheat endosperm. Later work by Chick showed that wheat germ protein can effectively supplement the wheat gluten protein. Hove and Harrel⁷ have recently reinvestigated the problem using the rat growth method of Osborne, Mendel and Terry⁸ whereby the test food is added to a ration which is complete in everything but protein and the biologic value is calculated as the ratio of the body weight gain to the amount of protein ingested during the experimental period. By this method, wheat germ protein was found to be about equal to the protein of skim milk and boiled egg white. Furthermore, the wheat germ protein and casein were found to be equally effective in supplementing poor protein diets. Thus it has been fairly well established that wheat germ is an excellent protein source which should not be neglected.

B Complex.—The following values for B vitamins in wheat germ appear in the literature:

	Mg. per 100 Gm.	
	Range	Typical Figure
Thiamine	1.9-4.7	3.0
Riboflavin	0.5-1.2	0.7
Niacin	3.4-6.9	6.0
Pyridoxine	0.9-1.5	
Pantothenic acid	1.5-3.5	
Biotin	0.045	
Inositol	250	
Choline	410	
Paraaminobenzoic acid	0.10	

The main reason for the variation is probably related to the presence of bran and flour. The work of Barton-Wright⁹ of Hinton¹⁰ and of Andrews¹¹ has shown that of the embryo, bran and flour constituents of "wheat germ" the bran is richest in niacin. The aleurone and scutellum tissue associated with the germ contains the most thiamine, while the pure germ itself is richest in riboflavin and is therefore an excellent source of thiamine and riboflavin and furnishes considerable amounts of the other B vitamins as well.

CORN GERM

The following figures have been given for defatted corn germ: protein 20-24.5 per cent, fat 2.0 per cent, ash 9.6 per cent and moisture 8 per cent. More than half the ash is phosphorus, and the iron content (0.03 per cent) is considerably higher than that in wheat germ. Mitchell and Beadles¹² have studied the protein and report that it is 85 per cent as digestible as that of beef round and its biologic value for the growing rat is as high as that of beef round. They also report figures of 4.18 per cent crude fiber, 6.9 per cent water, 21.2 per cent crude protein and 2.56 mg. of thiamine per hundred grams in the sample they studied. The VioBin Corporation reports the following values for B vitamins in corn germ:

	Mg. per 100 Gm.
Thiamine	2.5-3.5
Riboflavin	0.6
Niacin	4.5
Pantothenic acid	1.4

Conner and Straub¹³ have reported similar figures for thiamine and riboflavin, while Strong (unpublished data) has checked the foregoing figures for niacin, riboflavin and pantothenic acid.

SUMMARY

Wheat and corn germs are a good source of high quality protein. The thiamine content is about three times as high as whole grain cereals, and one fourth to one fifth as rich as average

brewers' yeast. The riboflavin content of grains is largely concentrated in the germ and the actual amount is about equal to that of dried whole eggs, about one half of that of dried milk and about one third of that of whole liver. Wheat and corn germs cannot be considered rich sources of niacin. The amount of niacin in wheat germ is equal to that in the whole kernel, and the amount in corn germ is somewhat higher than the whole corn kernel, since corn is lower in niacin than wheat. The germ is also a relatively good source of pyridoxine and pantothenic acid and other members of the B complex. While wheat and corn germ are not exceptionally rich in any of the B vitamins, they may be regarded as good natural sources of these factors and may be used effectively either directly or as supplements to other less nutritious foods in the human diet.

Council on Physical Medicine

THE COUNCIL ON PHYSICAL MEDICINE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. THIS COUNCIL WAS FORMERLY KNOWN AS THE COUNCIL ON PHYSICAL THERAPY.

HOWARD A. CARTER, Secretary.

WESTERN ELECTRIC TELEPHONE TYPE AUDIPHONE, MODEL J-1 ACCEPTABLE

Manufacturer: Western Electric Company, Inc., 120 Broadway, New York 5.

This is a carbon type hearing aid with a transmitter, a mechanical amplifier and a magnetic receiver. Two receivers were furnished for examination, the #714B and 714C types. The amplifier and sound pick-up work on the principle of a telephone transmitter. The device was investigated by the Council and the results are as follows.

Weights and overall dimensions of the various parts:

Transmitter, 3 inches by $\frac{7}{8}$ inch (circular in shape).

Receiver $\frac{3}{8}$ inch in diameter.

Amplifier $1\frac{1}{8}$ inches by 1 inch by $1\frac{1}{8}$ inches.

Weight of transmitter, receiver and amplifier 6 ounces.

Battery weighs 9 ounces.

Total weight of instrument 15 ounces

Battery.—Voltages and current drains are as follows:

Audiphone Battery GB-145, $4\frac{1}{2}$ volts.

Current drain at $\frac{1}{4}$ volume 30 milliamperes.

Current drain at $\frac{1}{2}$ volume 40 milliamperes.

Current drain at full volume 50 milliamperes.

All required data have been furnished by the manufacturer, such as response curves, descriptive booklet and directions.

Acoustical Gain.—The physical examination was made as follows: Average of observations of two trained observers using fitted ear molds were seated 5 feet from loud speaker which delivered frequencies of pure sine wave characteristics.

Receiver	Volume Control Set at	Frequency							
		256	512	1,024	1,448	2,048	2,896	4,096	
714C	$\frac{1}{2}$	1	2	3	6	4	10	3	Decibels
714C	$\frac{3}{4}$	2	3	7	8	8	11	4	Decibels
714B	$\frac{1}{2}$	0	0	3	5	3	10	3	Decibels
714B	$\frac{3}{4}$	2	2	5	9	10	13	3	Decibels

Physical and Mechanical Features.—The instrument consists of a black plastic molded case circular in form and pleasing in appearance. No particular change has been made in the actual appearance of the instrument from that of the previously accepted model. Also as in the previous model the carbon amplifier is connected directly to its own battery source.

Performance.—In general the instrument performs as represented. The specific advantage over previous models of this type is that the microphone operates in both vertical and horizontal positions. This is a distinct improvement. The volume control operates smoothly and is effective throughout the entire range. There is a minimum of case noise and no feedback squeal with a properly fitted ear mold.

Recommendations.—It must be remembered that this is a carbon instrument of the so-called "telephone type" and therefore cannot be judged on the basis of present requirements for vacuum tube hearing aids. The present model is an improvement over the one originally accepted by the Council on Physical Therapy. The workmanship is first class.

Despite the fact that the overall gain is not high, and that the gain for specific frequencies is also not comparable to any vacuum tube aids, the Council believes that this type of aid does serve a useful purpose. The Council on Physical Therapy voted to accept the Western Electric Telephone Type Audiphone Model J-1 for inclusion in its list of accepted devices.

OTARION HEARING AID (MODEL A-2) ACCEPTABLE

Manufacturer: Otarion, Incorporated, 448 North Wells Street, Chicago.

Model A-2 is a vacuum tube hearing aid consisting of three tubes, a transmitter, a crystal receiver and a battery unit held in a leather case. This model comes in four combinations, namely (1) red dot, maximum low frequency suppression, (2) orange dot, moderate low frequency suppression, (3) green dot, slightly low frequency suppression, and (4) black dot, no suppression. Two instruments were submitted, No. 3348, red dot, and No. 3351, black dot.

Model A-2, No. 3348 (red dot): Transmitter, $3\frac{3}{8}$ inches by $2\frac{3}{8}$ inches by $\frac{5}{8}$ inch, weight 4 ounces. Receiver, crystal, $\frac{7}{8}$ inch in diameter. Batteries, cords and receiver, weight 10 ounces. Total weight of the entire instrument, 14 ounces.

Batteries.—Voltages and current drains are as follows: A-battery, 1.5 volts; current drain at $\frac{1}{2}$ volume, 57.5 milliamperes. B-battery, 45 volts; current drain at $\frac{1}{2}$ volume, 1.5 milliamperes.

The instrument was examined in a laboratory acceptable to the Council. The following data are the average of observations of two trained observers using fitted ear molds seated 5 feet from loud speaker delivering frequencies of pure sine wave characteristics:

Volume Control	Frequency								
	Set at	256	512	1,024	1,448	2,048	2,896	4,096	
$\frac{1}{2}$		4	- 5	7	16	14	10	13	Decibels
$\frac{3}{4}$		8	10	14	18	19	18	23	Decibels

Model A-2, No. 3351 (black dot): Transmitter, $3\frac{3}{8}$ inches by $2\frac{3}{8}$ inches by $\frac{5}{8}$ inch, weight 4 ounces. Receiver, crystal, $\frac{7}{8}$ inch in diameter. Batteries, cords and receiver weight, 10 ounces. Total weight of the entire instrument, 14 ounces.

Batteries.—Voltages and current drains are as follows: A-battery, 1.5 volts; current drain at $\frac{1}{2}$ volume, 58 milliamperes. B-battery, 45 volts; current drain at $\frac{1}{2}$ volume, 1.1 milliamperes.

Acoustical Gain.—The following data are the average of observations of two trained observers using fitted ear molds seated 5 feet from loud speaker delivering frequencies of pure sine wave characteristic.

Volume Control Set at	Frequency							Decibels
	256	512	1,024	1,448	2,048	2,896	4,096	
$\frac{1}{2}$	12	14	17	20	12	9	15	Decibels
$\frac{3}{4}$	21	20	24	25	20	13	20	Decibels

Physical and Mechanical Features.—The instrument consists of a small and compact black plastic case and is of smooth appearance. The on and off switch and volume control is a small button placed on the left hand side of the instrument. This operates fairly easily. The construction of the instrument is of the highest type. All electrical connections are well made, and the disposition of the parts is unusually compact. The microphone is well cushioned against any possible jarring.

Otarion Hearing Aid
Model A-2

Performance.—The instrument operates in a very satisfactory manner and performs quite as represented. There is practically no feedback squeal even at high intensities and little if any distortion at high levels. Case noise and cord noise are minimal.

The Council on Physical Therapy voted to accept the Otarion Hearing Aid, Model A-2 (four combinations), for inclusion in its list of accepted devices.

SATURDAY, JULY 22, 1944

PHYSICAL FITNESS PROGRAM

The great victories which are being won by American troops in war zones all over the world are not being won by men who are physical weaklings or degenerate types of manhood. In this, as in previous wars, the American soldier has proved himself to be about as competent a fighter as the world can produce. He represents a selection of the best physical specimens that the nation has developed; to them have been applied the technics for physical and military training that the years have proved to be efficient. In selecting the men who now constitute our armed forces, 33,000 doctors and 10,000 dentists participated as members of various boards. Let the people remember that this service was given by these overworked and harassed physicians without any remuneration other than the satisfaction of having participated in the war effort.

As shown by the article of Colonel Leonard G. Rowntree in this issue of THE JOURNAL (page 821) the standards of physical fitness for military service have varied from time to time as the needs for manpower increased. The level of the requirements depends on the number of men needed in the military services, the urgency of the need, the size of the manpower pool and the relative need for men for military service or for industry. In the course of these studies a considerable residue of men not physically fit even for training became apparent. On page 825 is a list of the principal causes for rejection of registrants who were placed in class 4-F. Not all of those thus rejected can be made fit even by the application to the problem of everything that medicine now knows. About 35 per cent of the total were rejections for mental disease, mental deficiency, including illiteracy, and neurologic disorders. However, a deduction of about 1,500,000 men in these categories would still leave about 2,500,000 who could be benefited by the application of proper medical treatment. Many of them could be made to meet the needs of the armed forces.

The rehabilitation of those physically disabled is one problem. The creation of a state of physical fitness among young people in general is another problem. Thirteen per cent of young men entering the University of Illinois¹ could not swim at all, 64 per cent could not swim 50 yards, 3.1 per cent could not climb themselves once, 25.9 per cent could not climb themselves five times, 24.1 per cent could not jump an obstacle waist high, 50 per cent could not make the muscles of the abdomen hard enough to resist a fist pushed into the abdomen by an examiner, 79 per cent could not lift the legs from the floor twenty times when lying on the back and then do twenty sit ups in succession. Evidence of this type lends support to the charge by Colonel Rowntree that many Americans are flabby, soft, pampered and in need of conditioning. Physical fitness requires development. It is a bodily state in which the tissues have power and efficiency. The basic material of the American body is sound; it needs training.

The figures cited by Cureton for young men entering the University of Illinois are fully supported in the statements of Dr. Carl A. Wilzbach, commissioner of health of the city of Cincinnati, who reports in this issue of THE JOURNAL (page 828) on the medical and dental examinations of junior and senior high school students in Cincinnati. An inventory in the form of a health examination was made for 5,000 students. A program of correction utilizing the medical profession was established. Dental defects and disturbances of vision and hearing and particularly conditions related to the heart were given serious consideration. The results of these endeavors indicate that the returns in the way of improved health far more than repay the effort and the funds expended in a program of this kind.

Industry too is giving serious consideration in these times to the problem of physical fitness. Dr. W. P. Jacobs points the way to proper planning for physical fitness in industry in his article in this issue of THE JOURNAL (page 831). Properly he emphasizes that physical fitness is a personal and individual problem. While industrial programs of recreation and sports are built around mass action, their success is dependent on the correct diagnosis of the needs of each individual and the extent to which the individual embraces the opportunity to become fit. Particularly needed is an educational program directed along these lines.

A number of tests have been developed by medical science to determine physical fitness, particularly motor skills. In the development of such procedures Dr. J. Roswell Gallagher of Phillips Academy in Andover, Mass., and Dr. Lucien Brouha of the Hygiene Depart-

1. Cureton, T. K.: The Unfitness of Young Men in Motor Fitness, J. A. M. A. 123: 69 (Sept. 11) 1943.

ment of Harvard University have contributed greatly (page 834). They too emphasize the desirability of a body building program for every healthy person. They point out also that a proper physical education program requires more than calisthenics. The introduction of games and competitive sports which develop endurance and which add interest to physical conditioning is an important part of the program for producing physical fitness. They too find that activities leading toward physical conditioning cannot be beneficial unless the person has been found medically fit and unless the program for physical fitness is planned to suit his needs.

In 1943 President Roosevelt created a national committee on physical fitness under the egis of the Federal Security Agency with Mr. John B. Kelly as chairman and Colonel Rowntree as vice chairman. At the invitation of this committee the Board of Trustees of the American Medical Association with the support of the House of Delegates has authorized participation of the American Medical Association on a joint committee of the American Medical Association and the National Committee on Physical Fitness to be charged with development and operating a program for improving physical fitness throughout the nation during the year beginning September 1. Such a program would include evaluation of the physical state of our young men and women and increase the activities and responsibilities of schools and colleges in physical education, also improve opportunities for gaining physical health and enlist the active support of industrial, social, religious, patriotic, professional and other groups. The members of the joint committee, meeting under the chairmanship of Colonel Leonard G. Rowntree, includes Mr. A. H. Pritzlaff, past president of the American Association of Health, Physical Education and Recreation; Mr. Arch Ward, sports editor of the *Chicago Tribune*; Dr. Hiram A. Jones, state director of physical fitness for New York; Dr. William P. Jacobs, president of Presbyterian College, Clinton, S. C.; Dr. John W. Studebaker, commissioner of the U. S. Office of Education, and, representing the American Medical Association, Dr. Roscoe L. Sensenich of the Board of Trustees; Dr. Louis A. Buie of the Mayo Clinic, Rochester, Minn.; Dr. Morris Fishbein, editor of *THE JOURNAL*; Major General George F. Lull, Deputy Surgeon General of the U. S. Army, and Dr. William D. Stroud of Philadelphia.

This committee held its first session in Washington on July 14, at which time plans were inaugurated which are certain to eventuate in a campaign to interest the American people in the program for physical fitness and to bring increased health and efficiency to our nation.

ETIOLOGY OF PRIMARY ATYPICAL PNEUMONIA

Eaton and his collaborators¹ have investigated the agent in sputums and lung tissues from certain cases of atypical pneumonia. With this agent they were able to produce pulmonary lesions by primary intranasal inoculation of cotton rats. Evidence is presented that this agent has been adapted to chick embryos and that it is neutralizable by serums taken during convalescence from patients with primary atypical pneumonia. The authors point out the difficulties and confusion introduced into studies of this kind by previously unrecognized latent respiratory viruses of rodents. About 370 cotton rats were inoculated intranasally with sputums from 128 persons with atypical pneumonia and with suspensions of lung tissue from 15 patients who had died of the disease. Nonbacterial lung lesions were observed in 28 per cent of the animals, an incidence over six times as great as was seen in control animals. Hamsters were inoculated with five specimens of human material which have produced lesions in cotton rats. A virus was apparently transmitted to cotton rats from 10 of 18 patients in whom the presence of cold agglutinins was demonstrated. The lung lesions in the two species of animals were similar. Continued serial passage in 9 cases resulted in the eventual establishment of an agent in the cotton rats which consistently produced lung lesions; and in 4 cases this result was repeated, starting with the original material. The agent in cotton rats which was responsible for the production of lesions in the animals of the later passages was, however, not identical with the virus in the human material. This was suspected when neutralization by convalescent human serum could not be obtained regularly, although homologous immune rabbit or cotton rat serum readily neutralized these agents. Further investigation showed that the agent most frequently obtained in the serial passages was a latent pneumonia virus present in cotton rats. Despite the presence of these contaminating agents, some evidence from reinoculation experiments suggested that the original human virus was carried for several passages in cotton rats.

A sample of bacteriologically sterile human lung tissue from a patient with atypical pneumonia and filtered broth suspensions of 4 sputums were inoculated into the amniotic sac of chick embryos. Suspensions of the lungs, trachea and amniotic membrane of chick embryos of the third to fifteenth passages of one strain consistently produced lung lesions in hamsters after intranasal inoculation, but only about 30 per cent of the cotton rats inoculated with this material developed lung lesions. The lesions resulting from inoculating with chick embryo suspensions were similar in gross and microscopic appearance to those found in animals inocu-

1. Eaton, Monroe D.; Meiklejohn, Gordon, and Van Herick, William: Studies on the Etiology of Primary Atypical Pneumonia: A Filtrable Agent Transmissible to Cotton Rats, Hamsters and Chick Embryos, *J. Exper. Med.* 79: 649 (June) 1944.

lated with human material. The experiments involving passage in chick embryos with human lung tissue were successfully repeated. In 2 cases the virus was successfully adapted from sputum to the chick embryos and carried in serial passages.

The virus isolated from cases of atypical pneumonia is apparently not a member of the psittacosis-lymphogranuloma group, as demonstrated by the failure to infect mice by the intranasal route, the consistent absence of characteristic elementary bodies in impression smears of infected lung or chick embryo tissues, differences in gross and microscopic pathologic conditions and lack of antigenic relationships. The virus described seems to be propagated more readily by amniotic inoculation into chick embryos than by intranasal passage in animals. Evidence of infection of the chick embryo is based on the demonstration of small to moderate size lung lesions in cotton rats and hamsters inoculated intranasally, and neutralization by convalescent serum was indicated by inhibition of these lesions.

The question as to what proportion of all cases of primary atypical pneumonia is caused by the virus described has not been answered. This can probably be done by neutralization tests in a large series of cases.

Current Comment

NEW AND NONOFFICIAL REMEDIES NOW AVAILABLE

The 1944 edition of New and Nonofficial Remedies is now available. Each chapter has been revised to bring to the reader the present consensus of actions, uses and dosage of the preparations included. Included in this new edition are chapters on allergenic preparations, analgesics and antipyretics, anesthetics, anti-infective agents, autonomic drugs, cardiovascular agents, central nervous system stimulants, diagnostic aids, diuretics, hormones, sedatives and hypnotics, serums and vaccines and vitamins. Of the remaining chapters one promises to be of increasing importance: it is concerned with the actions and uses of contraceptive preparations. This section is a new addition to the book. Another addition of great practical importance is a list of tables of approximate equivalents of doses, apothecaries' and metric systems. The latest edition of New and Nonofficial Remedies adequately supports one of the functions of the Council on Pharmacy and Chemistry: "to advise the medical profession concerning the status of medicinal articles." A companion volume that is also available is the Council's Annual Reprint of Council Reports, which contains reports on articles declared unacceptable for inclusion in N. N. R. during 1943, articles omitted from N. N. R. and nineteen reports of general educational nature. For example, one may find extensive reports on the history of the use of the apothecary and metric systems, nomenclature and identification of endocrine preparations now on the market, use of estrogens in the

treatment of prostatic cancer, use of cod liver oil preparations on the skin, status of xanthine compounds, local use of sulfonamides in dermatology, treatment of Trichomonas vaginitis, and conception control. Truly, these books represent a fitting printed record of the Council's unselfish efforts to promote rational therapeutics.

EVAPORATED MILK

Over a year ago¹ THE JOURNAL called attention to the need for assistance from the medical profession in securing proper utilization of the available supply of evaporated milk. Now it is necessary to urge physicians again to avoid prescribing evaporated milk by named brands. A severe shortage in supplies of evaporated milk has again developed in certain parts of the United States, chiefly along the eastern seaboard south of Pennsylvania. Probably the supply for the country as a whole for 1944 and 1945 will be somewhat decreased. Plans are being made to assure the needs of infants by instituting new rationing procedure. In addition, the support of the medical profession is needed if the babies are to get what they require. Not all brands of evaporated milk can be made continuously available in all the localities. The Subcommittee on Medical Food Requirements of the Committee on Drugs and Medical Supplies of the National Research Council considered this problem at a meeting on March 29, adopting the following resolution:

All brands of evaporated milk, whether or not irradiated, meeting the requirements of the Food and Drug Administration, are of sufficiently uniform composition to be used interchangeably for the feeding of infants and children. However, consideration should be given to whether or not the milk is irradiated or fortified with vitamin D and the extent of such fortification. It is further recommended that distribution should be facilitated by all means available.

A recent survey was made of all types of distribution of evaporated milk in a number of cities as well as among independent grocers in rural areas of the section of the country most affected by the present shortage. In many cases the shortage proved to be not a shortage of evaporated milk but a shortage of certain favorite brands. Less well known brands were available but not moving. A typical complaint from a mother in North Carolina stated "I have a baby 3 months old who has been taking X brand milk since he was born. My physician strongly advises against changing to any other brand. I now find that it is increasingly difficult and almost impossible to obtain it. . . ." Physicians can do a real service to their patients and their country by explaining to mothers that all brands of evaporated milk must meet federal standards effective since July 17, 1940 and enforced by the Food and Drug Administration. If the favorite or accustomed brand is not available, satisfactory results can be expected from the use of less familiar brands, provided consideration is given to whether the milk selected is irradiated or fortified with vitamin D. If the milk selected is not so fortified, supplementation of the diet or formula with this vitamin can be provided separately.

MEDICINE AND THE WAR

ARMY

FLIGHT SURGEONS IN BURMA

A specially organized unit of five flight surgeons and eight enlisted technicians made military medical history in Burma's jungle wilds by bringing hospital type care almost into the front lines. This unit, aided by five other enlisted men, ran what amounted to a small hospital, operated first aid stations in the field and participated in all air borne expeditions. Major Robert C. Page, command surgeon of the unit, returned to the United States recently and told the story of the medical chapters in the adventures of Col. Philip Cochran's first air commando force in Burma. He and his staff established "sick inn" in a tea planter's cottage at the air commando base in Assam not far from the Japanese lines and more than 200 miles from the nearest army general hospital. "Sick inn," set down by air freight in an area which had no rail or motor roads, had 36 beds with white sheets and most modern hospital conveniences, such as electric refrigeration and washing machines. But it was not a hospital by military definition. Neither was it a dispensary. It had too small a staff for a station hospital and too much laboratory and medical apparatus for a dispensary. Major Page stated that "military necessity was final authority for everything we did. This was the first time an air force had been called on to transport, supply, defend and act as sole communications channel for a ground force operating far behind the enemy's front. There was no table of organization for this pioneer operation and we all improvised."

After being assigned by the Air Surgeon's Office to fulfil a request from the commanding general, AAF, for five flight surgeons with highly professional qualifications, the ability to fly an airplane and a desire for combat duty, Major Page, himself a specialist in internal medicine, selected Capt. Peter A. Reirson, Moscow, Idaho, specialist in surgery and a pilot; Capt. Weldon C. Murphy, Amarillo, Texas, eye, ear, nose and throat specialist and a pilot; Capt. Donald C. Tulloch, Ogdensburg, N. Y., general practitioner and a pilot, and Capt. Cortez F. Enloe, Manhasset County, Long Island, N. Y., trained in psychiatry and medical administration. The enlisted men were picked for ability to do at least two medical department jobs in addition to the one to which they were formally assigned. They were responsible for turning a rundown cottage into a mosquito proof, spotless and comfortable sick bay complete with a victory garden.

In addition to the officers flying cargo, bomber and pursuit aircraft and gliders, the air commando force also had a group of sergeants who held pilot's ratings. These "flying sergeants" were the pilots of the L-1s and L-5s, the "grass-hoppers" or "flying jeeps" of the AAF. These airplanes, together with the Fox Moths of the British Rescue Service, were responsible for the bulk of air evacuation of Chindits from Jap territory.

During the period Major Page had an opportunity to observe this operation in Burma, more than 2,000 casualties were evacuated. He states that "these little planes can carry one litter or a litter and a sitter patient, and the things the flying sergeants have done with them are incredible. Sometimes they would evacuate casualties from one end of a flying field while the Japs held the other end, actually flying over the heads of the enemy to escape. In one case 40 wounded men lay in a jungle clearing surrounded on three sides by Japs. Soon the tiny airplanes came hopping over the tree tops. They turned and glided swiftly into the clearing, two at a time. Under fire, each loaded a stretcher case and 2 wounded men who could walk and in a few minutes took off again for their base. They kept coming in until they had pulled out every one of the 40 from under the Jap's noses."

This method of front line air evacuation was originated in this theater of operations by the British, but it was not brought up to full potentialities until the arrival of the air commandos.

ARMY GRADUATES SPECIALLY TRAINED PSYCHIATRISTS

One hundred and forty medical officers who were given special training in three schools of military neuropsychiatry in the New York area graduated July 7 and were ordered to duty in army general hospitals to aid in treatment of psychiatric cases. Most of the officers were first lieutenants who recently completed nine month internships followed by special courses at the Army Medical Field Service School, Carlisle Barracks, Pennsylvania, and in general hospitals throughout the country, after which they entered the schools of military neuropsychiatry for three months' intensive study. Classes were conducted at the Mason General Hospital, Brentwood, L. I., the Columbia University College of Physicians and Surgeons, and Bellevue Hospital of New York University under the direction of leading psychiatrists and neurologists in civil and military life. One feature of the training schedule was observation by student officers of psychiatric examining procedures in operation at the New York City induction station. Medical officers returning from overseas and leading psychiatrists in civilian practice served as special lecturers.

Col. William C. Porter is director of the school at the Mason General Hospital. His assistants are Lieut. Col. Ralph T. Collins, Albany, N. Y., who had extensive service in Italy; Lieut. Col. Baldwin Keyes, Philadelphia, former professor of psychiatry at Jefferson Medical College, Philadelphia, who has seen service in Africa; Major William Dunn, New York, who served in the South Pacific, and Major James O'Leary, a neurologist, St. Louis.

The two schools in New York were under the general supervision of Capt. Norman Reider, Los Angeles. The course at Columbia University was under the direction of Dr. Nolin D. C. Lewis, director of the New York Psychiatry Institute and Dr. Tracy Putnam, director of the New York Neurological Institute. Dr. S. Bernard Wortis, professor of psychiatry at New York University and chief psychiatrist at Bellevue Hospital, was director of the school there.

REHABILITATION CENTER FOR BLIND

A rehabilitation center where blinded veterans of all branches of the service will receive extensive training to fit them for successful civilian lives recently opened at a former boys' school at Avon, Conn. All blinded servicemen will be sent to the center after they have received maximum benefit from medical and surgical treatment in service hospitals. The new installation, which was leased from the Avon school, will be known as the Old Farm Convalescent Hospital and is under command of Col. Frederic Thorne. The purpose of the center is to provide additional training for the blind in personal and social adjustment. They will be given extensive prevocational training on a sampling basis to determine as far as possible those occupational fields in which they will have the best chance of success after discharge from the service. The center maintains a staff of about 100 specially trained civilian and military supervisors, including vocational advisers and occupational therapists. It is planned to increase the size of the staff proportionally in the event of an increase in the number of blind casualties. To date there are 185 blind casualties from all branches of the service. Not all of these suffered blindness in combat.

Instruction will be given in such different kinds of work as stenography, typing, filing, general clerical tasks, metal and wood working, operation of small concession-type stores, and specialized farm jobs. Whenever possible, arrangements will be made to provide facilities for special studies in which patients may be interested. A staff of blind instructors has been selected to assist in helping patients reconcile themselves to their handicaps and overcome them. These instructors will conduct classes

and personal interviews and will teach the men reading, writing and typing by the braille method. On completion of a patient's social adjustment training, the Veterans Administration will arrange for any additional training he will require to fit him for a job, will help him find a job and maintain contact with his employer in seeing that he makes satisfactory progress.

THIRTY-NINE ENLISTED WACS BECOME COMMISSIONED PHYSICAL THERAPY AIDES

Thirty-nine enlisted members of the Women's Army Corps recently completed physical therapy training of almost a year's duration and were formally commissioned second lieutenants in the Medical Department of the Army. In nine army hospitals located in various sections of the country, these former Wacs were ushered into their official status with varying ceremonies. Strength of the physical therapy organization is less than a thousand aides at present, but an active recruiting effort is being made to increase this number. Major Emma Vogel, director of physical therapy aides, Office of the Surgeon General of the Army, stated that "these former enlisted Wacs are becoming officers of the Army at a time when their services are in urgent demand throughout the world.

"The initial thirty-nine have done an outstanding job. Our training program has been so popular with them that additional courses have been provided. It is now possible for civilian women who meet all the requirements, to enlist in the Women's Army Corps for the express purpose of taking this training.

"Casualty accounts from our overseas engagements are potent evidence of the need for physical therapists. These women have the opportunity of treating our wounded soldiers returned from those battle fronts and of experiencing the deep spiritual satisfaction that comes from aiding a patient to overcome his disability."

ONE HUNDRED NEW HOSPITAL CARS UNDER CONSTRUCTION FOR THE ARMY

One hundred new "unit type" hospital cars are being built for the Transportation Corps, Army Service Forces, by the American Car and Foundry Company, the War Department announced recently, to facilitate the War Department's plan for progressive evacuation of wounded. The cars will be placed in service starting in September, before invasion casualties in large numbers reach the United States. At the same time, all of the 120 ward cars and ward dressing cars in the Army's possession are being converted to unit cars as quickly as this can be done without interfering with the movement of casualties. The principal reason for the conversion is to add a cooking range to each car. En route to junction points where hospital trains are broken up, medical dining cars, of which the army has forty, will continue to be used to feed the wounded. After the trains are broken up, the kitchens in the unit type cars will be used, thus eliminating delays occasioned when sections of hospital trains have had to await the arrival of railroad dining car facilities.

Authorization of the new cars is in keeping with the War Department's policy to get the wounded to army hospitals as near to their homes as is consistent with availability of beds and facilities for specialized treatment.

WOMEN MEDICAL AND SURGICAL TECHNICIANS NEEDED BY ARMY

Women Medical and Surgical Technicians are needed by the Medical Department of the Army. According to a plan just announced, women who are high school graduates and who have completed at least six months' training in a school of nursing or who have a certificate of graduation from a Red Cross Nurses Aide course will be enlisted in the Woman's Army Corps. After the completion of basic training women will be given additional medical and surgical technical training at Camp Atterbury, Indiana.

ARMY AWARDS AND COMMENDATIONS

Major Sam Gendel

The Legion of Merit Award was recently presented to Major Sam Gendel at Torney General Hospital, Palm Springs, Calif., where he is now chief of the general surgery section. The decoration was awarded by the commanding general of the United States forces in the South Pacific for "exceptionally meritorious conduct in the performance of outstanding service while operating a hospital in the South Pacific area." Dr. Gendel graduated from the University of California Medical School, San Francisco, in 1935 and entered the service in 1940. In 1942 Dr. Gendel established a field hospital on a South Pacific Island with only partially trained personnel to erect buildings, install equipment and act as nurses and technicians. He served with conspicuous success for fifteen months at this post, where his initiative, energy, sound judgment and personal example not only inspired the hospital personnel but contributed to the morale of the entire force. He gave freely of his time in treating the sick among the native population, thereby cultivating friendly relationships which were of great benefit to the force which he served.

Captain Archibald M. Adams

Capt. Archibald M. Adams, formerly of Lima, Ohio, was recently awarded the Soldier's Medal in Italy for exceptional heroism over and beyond the call of duty. The citation reads "For heroism at great risk of his own life on observing an Allied fighter aircraft crash and burst into flames, Flight Surgeon Capt. Archibald M. Adams rushed to the scene and, heedless of intense heat, exploding ammunition and imminent danger of the aircraft exploding, made his way to the cockpit, freed the unconscious pilot and carried him to safety. By his courage and heroism in risking his life to save the life of another, this man has reflected great credit on himself and the Armed Forces of the United States of America." Dr. Adams graduated from the University of Cincinnati College of Medicine in 1934 and entered the service in May 1942.

Major E. Aaron Pushkin

Major E. Aaron Pushkin, formerly of West Hempstead, N. Y., was recently awarded the Soldier's Medal. The citation accompanying the award stated that "On Feb. 8, 1944 near Auburntown, Tenn., an army truck overturned in a ditch by the roadside, pinning ten soldiers under it. There was great danger that the water flowing through the ditch would cause the vehicle to sink into the mud and kill all of them. Voluntarily and at the risk of his life he crawled under the truck, administered morphine to a number of the men and assisted in their removal." Dr. Pushkin graduated from the medical College of Virginia, Richmond, in 1937 and entered the service Sept. 26, 1940.

Captain Arthur Shainhouse

The Silver Star was awarded to Capt. Arthur Shainhouse, formerly of Brooklyn and now stationed in Italy, on June 10. The citation accompanying the award read "Capt. Arthur Shainhouse, medics, Brooklyn, led aid men on two occasions forward under heavy fire to the assistance of another organization. He gave medical attention to all wounded and made sure they were evacuated before returning to his aid station. Many lives were saved by his actions." Dr. Shainhouse graduated from Dalhousie University Faculty of Medicine, Halifax, Nova Scotia, in 1941 and entered the service July 27, 1942.

Captain Charles B. Skinner

Posthumous award of the Soldier's Medal has been made to Capt. Charles B. Skinner, formerly of New York. The citation read "During a training demonstration March 23, 1944 a soldier fell into the torrent of an icy mountain river in Blackwater Canyon near Davis, W. Va. Captain Skinner, with utter disregard for his own safety, lost his life in attempting to rescue the soldier from the turbulent waters." Dr. Skinner graduated from Columbia University College of Physicians and Surgeons, New York, in 1941 and entered the service Aug. 17, 1942.

MISCELLANEOUS

REORGANIZATION OF THE COMMITTEE
ON MEDICAL RESEARCH

Dr. Chester S. Keefer has been appointed Medical Administrative Officer of the Committee on Medical Research, and several divisions and a records section have been established. The titles of the divisions and the names of their heads are indicated. Dr. Keefer, the chiefs of the newly established divisions and the head of the records section have been assured that the entire organization of the Office of Scientific Research and Development stands ready to aid them and that every possible assistance will be extended to them in the conduct of their affairs.

Medical Administrative Officer: Dr. C. S. Keefer, 2101 Constitution Avenue N.W., Washington, D. C.

Division of Medicine: Dr. E. Cowles Andrus, chief, 2101 Constitution Avenue N.W., Washington, D. C.

Division of Surgery: Dr. John S. Lockwood, Chief, University of Pennsylvania Medical School, Philadelphia.

Division of Aviation Medicine: Dr. Detlev W. Bronk, chief, Johnson Foundation, Maloney Clinic Building, 36th and Spruce streets, Philadelphia.

Division of Physiology: Dr. J. T. Wearn, chief, 2101 Constitution Avenue N.W., Washington, D. C.

Division of Chemistry: Dr. M. C. Winternutz, chief, Yale University Medical School, 333 Cedar Street, New Haven, Conn.

Records Section: Dr. K. B. Turner, chief, 630 West 168th Street, New York.

Director: V. Bush.

HOSPITAL SHIPS FOR CONVOYS

Floating hospitals will soon be going to sea as part of America's regular convoy escorts. Recent Navy trial runs of the PCE (R) 853 (patrol craft escort, rescue) were made in Lake Michigan. The vessels contain bunks for 57 men and have complete hospital facilities, including a doctor, operating table, dispensary and x-ray machines and are being built by the Pullman-Standard Car Manufacturing Company, Chicago. The vessels will save many men the ordeal of long hours at sea without adequate medical attention. Like other PCE craft, these rescue ships are manned by 7 officers and 100 men. In addition to their rescue work these craft make excellent vessels for following up landing craft in invasions.

MEDICAL AID MAN AWARDED
SILVER STAR

Pfc. Russell L. Horn, formerly of McKinney, Texas, and now a medical aid man attached to a field artillery observation battalion, has been awarded the Silver Star for gallantry in action and for his courage under fire. The action that brought the award occurred in Italy in January. Although the enemy was firing a sustained barrage, Private Horn dressed the wounds of his injured comrades and directed their evacuation. He refused to accept medical aid for himself and leave the area until he had made certain that all other injured had been rescued.

REHABILITATION CENTERS FOR U. S.
MERCHANT MARINES

The Office of War Information recently announced that more rapid certification of disabled seamen and officers of the U. S. Merchant Marine to vocational rehabilitation centers has been arranged by the War Shipping Administration. Disabled men who received their disability in line of duty may receive surgical and medical treatment, hospitalization, therapeutic treatment, artificial appliances, vocational guidance and training, maintenance during training and placement at federal expense. Speeding up of the procedure by which disabled seamen obtain rehabilitation benefits was made possible through the Service Division of WSA. Applications are processed by the Service Division and forwarded to the Federal Security Agency. Qualified seamen and officers are then certified by FSA to the man's home state for vocational training and rehabilitation.

Delay previously encountered by a seaman in establishing eligibility for vocational rehabilitation has been eliminated.

The new procedure makes possible the rapid check of a man's record through offices of WSA and the U. S. Maritime Commission. An amendment to the rehabilitation law provided federal funds for vocational rehabilitation training of certain civilians, including seamen and officers of the United States Merchant Marine who proved they were disabled and handicapped in line of duty. WSA officials expect at least 5,000 seamen to apply for certification for vocation rehabilitation within the next few months.

PUBLIC HEALTH UNDER HITLER

L'Action française of March 10, 1944 (France) states that though it is difficult to draw up statistics on abortions the figure for the whole country is probably 1,000,000, compared with the 500,000 claimed by overoptimistic sociologists. Among the best means of fighting abortion, apart from legislative measures, there is antepartum allowance, which has already been introduced by private initiative in three factories. In the first factory the number of births rose from two during the twelve months preceding the introduction of antepartum allowances to eight during the twelve months following, in the second factory from five to eight and in the third from four to eight. During the same period the ratio of the number of births in these factories to the total number of births in the communes where the factories were situated rose from 1.3, 8 and 17 per cent to 8, 17.5 and 50 per cent respectively. Considering these remarkable results, the social committees should endeavor to obtain an extension of the antepartum allowance scheme to all industrial and commercial undertakings without delay.

Vichy Home Service, March 23 (France), broadcast part of a press interview granted by Dr. Ghasset on the question of converting certain watering places into cités sanitaires, as proposed by him at the last council of ministers. "Not only has the war prevented us building new hospitals; it has destroyed some of those we already had. The evacuation of the coastal districts has also reduced the possibility of opening new ones. We now lack 38,000 beds of the 150,000 we had before. Further, a certain number of hospitals have had to be evacuated from threatened towns. We have now to cope with the problem of providing hospital accommodation for from 2,000 to 3,000 sick people. The solution the Council of Ministers has adopted consists in equipping two or three small spas which are well situated and have been carefully selected. Since the war, hydromineral spas have been carrying on on a reduced scale; but the accommodation is there and we can therefore put up sick people who have been evacuated. The powers which I have been given by the Council of Ministers have enabled me to envisage with less anxiety the evacuation of certain hospitals situated in the threatened districts."

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, July 15, page 795)

MICHIGAN

St. Lawrence Hospital, Lansing. Capacity, 230; admissions, 6,897. Sister M. Assisium, Superintendent (interns).

NEW HAMPSHIRE

Sacred Heart Hospital, Manchester. Capacity, 163; admissions, 2,561. Sister M. Bernardus, R.N., Superintendent (mixed residencies).

NEW JERSEY

Muhlenberg Hospital, Plainfield. Capacity, 330; admissions, 6,136. Mr. John R. Howard Jr., Superintendent (interns, July 1, 1945).

VIRGINIA

DePaul Hospital, Norfolk. Capacity, 245; admissions, 7,512. Sister Inez, R.N., Administrator (2 interns, October 1).

WISCONSIN

St. Mary's Hospital, Madison. Capacity, 225; admissions, 7,065. Sister M. Bernadette, R.N., Superintendent (interns).

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

July 17, 1944.

The Cumulative Shortage of Physicians

Cognizance of THE JOURNAL'S warning of a cumulative shortage of 2,000 physicians a year in the United States, unless nondeferment policies of National Selective Service and the armed forces are changed, was taken at the Senate Subcommittee on Wartime Health and Education, presided over by Senator Claude Pepper, chairman.

Dr. Alan Gregg, director of the Medical Services Division of the Rockefeller Foundation, said "The time is rapidly approaching, if it is not already here, when, in order to produce 50 to 100 students even approximately adequate in their preparation, many medical schools will stand in serious need of their teachers now in military service; these men should be called back and assigned to duty in training the young military men now in the medical schools."

National danger inherent in a shortage of physicians in coming months and in the postwar period was brought to attention of the witnesses at the hearing through widespread publicity given American Medical Association views on the subject. Washington papers as well as the press of the country gave considerable display to THE JOURNAL editorial which warned of a tremendous number of reductions in graduates after the war unless an adjustment is made.

Emphasis was given to the seriousness of the situation by deans of the District of Columbia medical schools in press interviews, while the hearing on wartime health and education was in progress. They viewed with concern President Roosevelt's acceptance of the Selective Service order banning draft deferment of premedical students beyond July 1. "If deferment is refused of all except the young men now enrolled in medical and dental schools," said Rev. David V. McCauley, S.J., regent of Georgetown University Medical School, "it will be manifestly impossible in and after 1948 to fill even those vacancies in the professional ranks caused annually by death. . . ."

"The postwar period will reflect the loss for years," said Dr. John W. Lawlah, dean of the Harvard Medical School. He went on to say that medical schools had been led to believe that there is an acute shortage of medical men because of the number of Army requests for doctors to be commissioned. It is as important to the total effort, he stated, to train a man as a doctor as to train him to hold a gun. "All the deans feel that this action will make it difficult to recruit sufficient students for training," he said.

The ban will require medical schools to lower the "very high standard" they have tried to maintain, said Dr. Edward G. Reinhard, head of the Biology Department of Catholic University. This university, he pointed out, had lowered premedical requirements from four years of study to less than two.

"A deep concern," over the action taken, was expressed by Dr. Walter A. Bloodorn, dean of George Washington University Medical School.

The three day hearing on wartime health and education was keyed by Senator Pepper's statement that "it is a national tragedy that five million of our young men are unfit for military service at a time when manpower needs of the nation are so critical."

Selective Service is aware of the prevailing need of doctors, Col. Leonard G. Rowntree, chief of its Medical Division, revealed in his testimony. He called the necessary rejection by the armed services of men for combat service a "national disgrace," showing youth of the country to be flabby and soft. He said "Instead of a country of rugged, virile men, we have a lot of 5-D's, defective, disabled, deficient, disordered and diseased." In examination of one tenth of the population for military service, Colonel Rowntree said, "those examinations reveal that the country is ailing and that its youth is flabby and soft. It should have medical attention."

Gen. Lewis B. Hershey, director of Selective Service, testified that many fathers had to be taken into the armed forces because Selective Service had scraped the bottom of the barrel of physically fit single men and married men without children.

Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, suggested a better distribution of hospitals and health centers in the postwar period, pointing out that 1,200 U. S. counties with a population over 15,000 persons have no recognized hospital facilities. He estimated that 419,400 new and replacement beds are needed. His plan for future public health facilities called for erection of "base" hospitals with teaching facilities, centrally located in each state, surrounded by "district" hospitals in smaller, urban areas, and many "health centers" in rural areas. Constant ambulance service would be available for removal of serious cases from health centers to district or base hospitals.

In this vein Vice Admiral Ross T. McIntire, Surgeon General of the Navy, advocated clinics under the direction of the U. S. Public Health Service in each community with diagnostic facilities available for all citizens.

To the U. S. Public Health Service Paul V. McNutt, federal security administrator and chairman of the War Manpower Commission, gave credit for preventing epidemics during the war by scrupulous care in rat proofing and fumigating incoming ships and planes.

Planning for hospitals and medical centers was discussed by Dr. Victor Johnson, secretary of the Council on Medical Education and Hospitals of the American Medical Association, Dr. Claude Munger, chairman of the Council on Government Relations of the American Hospital Association, Dr. Vane M. Hoge, chief of the Hospital Facilities Section of the U. S. Public Health Service, and the health need of veterans by Col. W. C. Menninger, director of the Division of Neuropsychiatry, Medical Corps, U. S. Army, Brig. Gen. Frank T. Hines, administrator of the Veterans Administration and director of reemployment and retraining, Office of War Mobilization, and representatives of the American Legion, Veterans of Foreign Wars and Disabled War Veterans of America.

Members of the subcommittee are Senators Claude Pepper of Florida, chairman, James M. Tunnel of Delaware, Elbert D. Thomas of Utah, Robert M. LaFollette Jr. of Wisconsin and Kenneth S. Wherry of Nebraska.

The War Shipping Administration

One of the less publicized governmental medical departments which has done much to develop new ways of meeting specialized problems of this modern war is the medical service of the War Shipping Administration, of which Dr. Justin K. Fuller is medical director. Now the crew has the benefit of treatment from a pharmacist mate or hospital corpsman—on a cargo vessel he is known as junior assistant purser-pharmacist mate—and the crew lives "to-side amidships," in better ventilated, more comfortable, small group rooms, instead of poorly ventilated community forecastles that were damp, evil smelling and uninviting.

Dr. Fuller has found new opportunities presented through the war for safeguarding the health of merchant seamen, which of course means improved efficiency of the Merchant Marine. This is important, because on the Merchant Marine depends success of far flung battle forces depending solely on long supply lines. Outstanding development in medical service for the Merchant Marine is acceptance of merchant seamen in army and navy hospitals and dispensaries abroad, and repatriation of disabled seamen on hospital and other ships of the Army and Navy. Another significant service is provision of medical advice and social service help by officers of the Recruitment and Manning Organization of WSA and the United Seamen's Service for merchant seamen repatriates when they reach United States ports.

Maritime law requires that a medical officer be included in the crew of ships carrying more than thirty passengers, and

few ships carrying less than this number have had a doctor aboard, as a result. Until recently ships in the latter class have usually been without medical personnel. With bombing and strafing a constant hazard for the merchant ships WSA developed a hospital corps school at the Maritime Service Training Station, Sheepshead Bay, Brooklyn. The first class of 300 was graduated early in 1943, and it is expected that by the end of 1944 every merchant vessel operating under control of the agency will have a graduate of this school aboard. Other safeguards for merchant seamen include inspection of ship plans and ships under construction by Public Health Service sanitary engineers. A sanitary code laid down by the Public Health Service governs, among other things, taking on of water, elimination of cross connections in plumbing systems, disinfection and the disposal of sewage and garbage at sea, inside harbors and when tied at docks.

Ships' personnel have found helpful the new centralized supervision of ships' medicine chests and uniform provision of necessary medical supplies and equipment, including dried plasma, DDT powder and penicillin. Medical standards for enrollment have been determined with great care, which is said to have been reflected in a higher physical caliber of the 50,000 odd trainees graduated from training stations and ships of the

Maritime Service. Annual as well as "sign on" medical examinations are required.

Rehabilitation of disabled seamen is a part of the WSA medical problem. Seamen unable to return to sea are referred to the Federal Security Agency. Although exposed to the same risks as the armed forces, the merchant seamen is not as well protected by compensation, war risk insurance, certain medical benefits and rehabilitation. Casualties during periods of heavy shipping losses were greater than in any other group. Legislation is now under advisement aimed at correcting this situation.

Dr. Fuller is endeavoring to provide the best possible medical service for merchant seamen through the use of over-all activities of the Public Health Service, augmented by specialized facilities of the Hospital Divisions, Mental Hygiene Divisions, Venereal Division, Dental Section and Sanitary Engineering Section. His office as medical director of WSA operates as a unit of the Public Health Service out of the office of the deputy administrator for labor relations, manning, training and recruitment. Naturally, cooperation of medical services of other government and private agencies is solicited and used to the fullest extent. It is felt in responsible circles here that the program has justified itself.

WOMAN'S AUXILIARY

OFFICERS OF THE WOMAN'S AUXILIARY FOR THE COMING YEAR

Newly elected officers of the Woman's Auxiliary to the American Medical Association are as follows: Mrs. David W. Thomas, Lock Haven, Pa., president; Mrs. Jesse D. Hamer, Phoenix, Ariz., president-elect; Mrs. Eustace A. Allen, Atlanta, Ga., first vice president; Mrs. J. H. Hornberger, Roebing, N. J., second vice president; Mrs. A. H. Duemling, Fort Wayne, Ind., third vice president; Mrs. David Berg, Helena, Mont., fourth vice president; Mrs. Arthur A. Herold, Shreveport, La., constitutional secretary; Mrs. Harold F. Wahlquist, Minneapolis, treasurer.

Arizona

The Maricopa auxiliary of Arizona recently launched a drive for discarded woolen materials to be used for the Kenny treatment of poliomyelitis. Other counties were asked to help, and the plan was presented at the annual state convention, which was held in Phoenix, April 14-15.

Arkansas

Mrs. B. L. Ware was elected president of the auxiliary of the Sebastian County Medical Society of Arkansas at a luncheon meeting of the auxiliary recently. She succeeds Mrs. W. F. Rose.

The Pulaski County auxiliary held its regular meeting in March with the topic "Food and Its Importance to Good Health" as the subject of the evening. A dinner honoring the husbands was given March 31.

Colorado

The Larimer County auxiliary of Colorado has had an evening meeting and a luncheon meeting and been the guests of their medical society at a dinner. The medical society also entertained the wives of the men in service. This auxiliary has given a two years subscription to the *Reader's Digest* to the Larimer County Hospital. Dr. J. D. Carey and his daughter gave the hospital an oxygen tent and machine in memory of Mrs. Carey.

Iowa

Iowa has fifteen county auxiliaries, with a membership of 316. The Iowa auxiliary has two to four pages each month in the state medical journal, and reprints are mailed to each member. Mrs. K. M. Chapler, state chairman of press and publicity, has placed ten "doctors at war posters" in public institutions.

Michigan

The Ingham County auxiliary of Michigan held its Guest Day at the home of Mrs. L. M. Snyder recently. One hundred dollars was voted to the Red Cross. Dr. H. G. Batson spoke on "Trends in Modern Therapy." The St. Claire County auxiliary held its March meeting at the Chateau in Port Huron. Dr. J. A. Dunn spoke on "The Latest Developments in Food."

Minnesota

Kandiyohi-Swift-Meeker County Medical Auxiliary was reorganized at a meeting held recently at the home of Mrs. Richard Anderson in Willmar. There were fifteen present, and Mrs. Hans Jolmson, Kerhoven, was elected president.

The Hennepin County auxiliary held an all day health institute March 3. Three hundred persons including presidents of all of Minnesota's clubs attended. Dr. Walter C. Alvarez of the Mayo Clinic spoke on "Why Women Are Nervous." A film entitled "Fight Syphilis" and another "Fighting Tuberculosis in Hennepin County" were shown. Dr. W. A. O'Brien spoke on "Tropical Diseases: A Postwar Problem." Other talks were given including a talk on the Wagner-Murray-Dingell bill.

Missouri

At a recent meeting the Missouri auxiliary elected Mrs. J. B. McCubbin of Fulton president and Mrs. Harry Gilkey of Kansas City president-elect. A breakfast honoring the past president and a luncheon were the only social events. An address was given by Dr. W. W. Bauer, Director of the Bureau of Health Education of the American Medical Association.

Ohio

At a meeting of the Woman's Auxiliary to the Toledo Academy of Medicine recently the program consisted of brief, informal talks by members whose husbands are in service; New Guinea, South Pacific, Hawaii, England, New Hebrides, Aleutians and Iran were the countries discussed.

Oklahoma

The membership report for Oklahoma is Tulsa 133 members, Oklahoma City 114 members, Ada 14 members, Shawnee 16 members and Norman 18 members.

West Virginia

West Virginia held its twentieth annual meeting May 15-16 at Wheeling. Capt. W. M. Sheppe (Mc), U.S.N.R., gave an address on "Recent Advances in Medical Care of Naval Personnel." Mrs. Eben J. Carey, National president, was one of the honor guests at the luncheon.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Hospital Receives Physician's Equipment.—The late Dr. Charles S. Hale, who died in March at Cisco, Texas, bequeathed all his medical and surgical equipment to St. Bernard's Hospital, Jonesboro. Newspapers May 1 reported that the hospital had already received the equipment.

CALIFORNIA

Venereal Disease Control Institute.—An institute on community control of venereal diseases opened at the University of California, Los Angeles, July 17, to continue for three weeks. The institute is in charge of Dr. Nels A. Nelson, Baltimore, deputy state health officer, bureau of communicable diseases, Maryland State Department of Health.

Personal.—Morris A. Stewart, Ph.D., associate professor of parasitology, University of California, Berkeley, is to spend three months in Bolivia with headquarters in Santa Cruz. *Science* reports that Dr. Stewart's work on parasitic diseases and means for their control will be used by the Bolivian government in its program for the economic development of the country.

Medical Missionaries Return to India.—Drs. Arthur E. Coyne, Takoma Park, Md., and Theodore R. Flaiz, Watapo, Wash., medical missionaries, will return to Surat, India, according to the *Medical Evangelist*. After his graduation at the College of Medical Evangelists, Loma Linda, in 1918, Dr. Coyne served six years in India. He later served as dean of the Los Angeles division of the college. Subsequently he has been serving in various hospital positions. Dr. Flaiz was in India from 1920 to 1932. After his graduation at the college in 1938 he served in the administrative offices in the Los Angeles division. Both physicians plan to travel with their wives to India by way of Portugal.

CONNECTICUT

Pharmaceutical Meeting.—"Does the American Public Want Prepaid Medical Care?" was the title of a paper by Dr. Creighton Barker, executive secretary, Connecticut State Medical Society, before the sixty-eighth annual meeting of the Connecticut Pharmaceutical Association, New Haven, June 22.

Memorial Issue to Dr. Trask.—The *Yale Journal of Biology and Medicine* devoted its May issue to the memory of the late Dr. James Dowling Trask, who at the time of his death in 1942 was associate professor of pediatrics at Yale University School of Medicine, New Haven.

Personal.—Dr. John S. Lockwood, acting director, Harrison department of surgical research, University of Pennsylvania School of Medicine, Philadelphia, has been named associate professor of surgery at Yale University School of Medicine, New Haven, effective July 1. —Dr. Edgar C. Yerbury has been appointed superintendent of the Connecticut State Hospital, Middletown, to succeed Dr. Roy L. Leak, who is resigning after holding the position since April 1922. —George R. H. Nicholson, headmaster of Kingswood School, West Hartford, was elected president of the Connecticut Society for Mental Hygiene at its recent annual meeting and Dr. Paul P. Swett, Bloomfield, was chosen vice president.

FLORIDA

Dr. Rowlett Resigns from State Board.—Dr. William M. Rowlett, Tampa, secretary of the Florida State Board of Medical Examiners since 1918, has resigned, effective July 15. Dr. Rowlett, who graduated at the Atlanta College of Physicians and Surgeons in 1909, served as president of the Florida Medical Association in 1939.

Special Society Election.—Alvin P. Black, Ph.D., professor of agricultural chemistry, University of Florida, Gainesville, was recently chosen president of the Florida Public Health Association. Other officers include Drs. Wieland W. Rogers, Jacksonville, E. Lucille J. Marsh, Tallahassee, vice presidents, and Edward M. L'Engle, Jacksonville, secretary-treasurer.

GEORGIA

Personal.—Dr. Abram J. Davis, Swainsboro, has resigned as health commissioner of Emanuel County to accept a similar position in Richmond County. —Dr. Charles L. Ridley, Macon, health officer of Bibb County, has been appointed chairman of the state department of public health.

State Medical Election.—Dr. Ralph Hill Chaney, Augusta, was chosen president-elect of the Medical Association of Georgia during its recent annual meeting in Savannah, May 9-12, and Dr. Cleveland Thompson, Millen, was installed as president. Dr. Edgar D. Shanks, Atlanta, is the secretary. The 1945 annual meeting will be held May 8-11 in Macon. Dr. Arthur W. Allen, Boston, delivered the Abner Wellborn Calhoun Lecture at the meeting, May 10, on "Gastric and Duodenal Ulcers."

IDAHO

Personal.—Dr. Virgil C. Belknap, Nampa, recently completed fifty years in the practice of medicine. —Dr. Jay C. Miller, Grand Island, Neb., has been appointed director of the Kootenai County Health Unit, succeeding Dr. Herbert L. Newcombe, Coeur d'Alene, who has resigned to enter private practice. Dr. Miller will be located at Coeur d'Alene.

ILLINOIS

Changes in State Department of Health.—Dr. Alexander William Burke, Chicago, was recently named acting chief of the state division of tuberculosis control in addition to carrying on his work as director of health district number ten, consisting of five counties. He fills the vacancy that occurred when Dr. Edward K. Steinkopf resigned to become medical director of the Pinehurst Sanatorium, Janesville, Wis. Dr. Henrietta M. Herbolzheimer, Chicago, has been appointed acting chief of the state division of maternal and child hygiene. Dr. Hugo V. Hullerman, Chicago, chief of the division, resigned to become secretary of the council on professional practice of the American Hospital Association (*THE JOURNAL*, June 17, p. 503). Dr. George G. Taylor, Chicago, has been appointed chief of the state division of venereal disease control, effective July 1, succeeding Dr. Herman M. Soloway, Chicago, who has resigned to reenter private practice. Dr. Soloway will continue with the department on a part time basis, serving as venereal disease control officer in the division of industrial hygiene.

Chicago

Granville Bennett Appointed Head of Pathology at Illinois.—Dr. Granville A. Bennett, professor and head of the department of pathology at Tulane University of Louisiana School of Medicine, New Orleans, has been appointed to a similar position at the University of Illinois College of Medicine.

Memorial Lecture to Honor Sanford Gifford.—The Chicago Ophthalmological Society is planning to establish a memorial in honor of the late Dr. Sanford R. Gifford in the form of a lecture on an ophthalmological subject to be delivered annually before the society. In an announcement the society states that it is hoped that many friends of Dr. Gifford will take this opportunity to contribute to this lecture fund in honor of the memory of one who made such noteworthy contributions to ophthalmology as an author, a clinician and an inspiring teacher. Contributions may be sent to Dr. William A. Mann, secretary of the Chicago Ophthalmological Society, 30 North Michigan Avenue.

IOWA

State Medical Election.—Dr. Ransom D. Bernard, Clarion, was chosen president-elect of the Iowa State Medical Society at its recent annual meeting and Dr. Maurice C. Hennessy, Council Bluffs, was installed as president. Dr. Robert L. Parker, Des Moines, is secretary. The next annual session will be held in Des Moines, April 19-20, 1945.

Narcotic Violation.—Dr. Chester F. Cashman, Hartley, pleaded guilty in the U. S. District Court at Sioux City, May 26, to a violation of the federal narcotic law. Dr. Cashman was sentenced to serve a term of imprisonment for three years. Sentence was suspended and he was placed on probation for a similar period, according to the U. S. Bureau of Narcotics.

KANSAS

Mr. Ebel Named Executive Secretary of State Society.—Mr. Oliver Ebel, Wichita, has been appointed executive secretary of the Kansas Medical Society, effective July 1. Mr. Ebel resigned a similar position with the Sedgwick County Medical Society to accept the new appointment.

MARYLAND

Conference on Cancer.—Section C of the American Association for the Advancement of Science will sponsor a conference on cancer at Gibsons Island, July 31-August 4. Among the speakers will be:

July 31

Dr. Albert Claude, New York, Topography of Cell Function.
Drs. Edward W. Shrigley, Madison, Wis., and Francesc Duran-Reynals, New Haven, Conn., The Biology of Virus Induced Tumors.
Alfred Taylor, Ph.D., Austin, Texas, Virus Production of Mammalian Tumors.

William Ray Bryan, Ph.D., Bethesda, Md., and Herbert Kahler, Ph.D., Virus Studies with Newer Techniques.

August 1

John J. Bittner, Ph.D., Bar Harbor, Maine, Inciting Influences in the Etiology of Mammary Cancer in Mice.
Howard B. Anderson, Sc.D., Bethesda, The Milk Factor in Breast Cancer in Mice.

Mary E. Maver, Ph.D., Washington, D. C., Serology of Tumor Cathesins.

Dr. Jacob Furth, New York, The Site and Time of Malignant Change in Leukemia of Mice.

August 2

Frank H. J. Figgie, Ph.D., Baltimore, The Relationship of Pyrrole Compounds to Carcinogenesis.

Louis F. Fieser, Ph.D., Cambridge, Mass., Discussion of Hydrocarbon Carcinogenesis.

Wilton R. Earle, Ph.D., Washington, Production of Malignancy in Vitro.

Dr. Harry S. N. Greene, New Haven, The Occurrence of Dependent and Autonomous Phases in the Development of Cancer.

August 3

Roger J. Williams, Ph.D., Austin, B Vitamins and Cancer.
Jesse P. Greenstein, Ph.D., Silver Spring, Enzymes and Cancer.

Dr. Harold P. Rusch and Carl A. Baumann, Ph.D., Madison, The Prevention of Experimental Liver Tumors by Dietary Means.

August 4

Heron O. Singher, The Effect of Inhibitory Agents on Normal and Malignant Tissue.

Dr. Curtis M. Flory and Dr. Furth, New York, Chemotherapeutic Studies on Leukemia.

MASSACHUSETTS

Dr. Dubos Returns to Rockefeller Foundation.—René J. Dubos, Sc.D., has resigned as George Fabyan professor of comparative pathology and tropical medicine, Harvard Medical School, Boston, to return to the Rockefeller Institute for Medical Research. Dr. Dubos resigned from his previous appointment at the institute as member on June 30, 1942 to accept the Harvard position.

MICHIGAN

Earl Burbidge Appointed Medical Director of Frederick Stearns and Company.—Dr. Earl L. Burbidge, Philadelphia, for the past three years with the medical research division of Sharp & Dohme, has been appointed medical director of Frederick Stearns and Company, Detroit, effective June 15. Dr. Burbidge graduated at the Washington University School of Medicine, St. Louis, in 1939.

Prevalence of Mosquitoes.—Six members of the U. S. Public Health Service are conducting a mosquito survey in Michigan to determine the prevalence of various mosquitoes. Adult mosquitoes and larvae from every county in Michigan will be collected and sent to the state health department headquarters in Lansing, where they will be studied by a member of the staff. *Public Health News* states that no effort will be made to cut down on the number of mosquitoes this summer but, if the study shows that they are a hazard to health in certain sections, control measures will be undertaken later.

Personal.—Dr. Leverett S. Woodworth, Detroit, was chosen president of the Michigan Hospital Association at its recent meeting in Chicago. —Dr. James R. Jeffrey Jr. has been named temporary superintendent of the Battle Creek Sanitarium, Battle Creek. —Dr. William P. Derck, Marysville, was honored at a dinner meeting of the St. Clair County Medical Society in recognition of his completion of fifty years in the practice of medicine. —Dr. Rudolph Robert Lang has resigned his commission in the U. S. Public Health Service. The *Bulletin* of the Ingham County Medical Society is reported to have said that Dr. Lang resigned because the public health service allows osteopaths to be commissioned.

MINNESOTA

Hospital Association Receives Award.—The Minnesota Hospital Association on May 14 received a plaque from the American Hospital Association for the "best hospital public education program in the nation for 1942 and 1943." Dr. Thomas E. Broadie, Ancker Hospital, St. Paul, was inducted into the presidency and Miss Dina Bremness, R.N., Glenwood Community Hospital, Glenwood, was named president-elect.

State Board Abandons Reciprocal Relations with Illinois.—The Minnesota State Board of Medical Examiners on May 12 acted to terminate reciprocal relations with the state of Illinois. According to the Minnesota board the action was the result of a refusal of the Illinois authorities to recognize a license issued by the Minnesota board to one who was the holder of a bachelor of medicine degree at the time of the examination rather than a doctor of medicine degree. It was stated that the action of the board is a mandatory provision of the Minnesota law.

License Revoked.—On May 12 the license to practice medicine of Dr. Orel Anson Kibbe was canceled by the Minnesota State Board of Medical Examiners because of his plea of guilty in the district court of Hennepin County, March 8, to a charge of performing an illegal operation. At the time he pleaded guilty Dr. Kibbe surrendered in open court his medical license and basic science certificate with a written request that they be canceled by the state board of medical examiners and the state board of examiners in the basic sciences (*THE JOURNAL*, June 10, p. 440).

Medical Art Show.—The Minneapolis Public Library on June 19 opened its first medical art display. Included in the exhibit are the works of a number of medical illustrators, including Russell Drake, Mayo Clinic; Jean Hirsch, head of the Medical Art Shop, University of Minnesota; Gladys McHugh, University of Chicago; Ralph Sweet, University of California Medical Center; Elizabeth Brodel of the Society of the New York Hospital; the Medical Fantasies of Daisy Stilwell, Modern Medicine, and the drawings of the late Dr. Harry B. Wilmer for his book *Huber the Tuber*. The exhibit includes a group of books showing the earliest examples of medical illustrations lent by the Surgeon General's Library in Washington and two Vesalius volumes, a 1783 edition by Shirley P. Miller, Ph.D., of the University of Minnesota and the 1934 edition from the library of Modern Medicine. The display also includes a group of prints from the art department of the public library. The exhibit will be open until July 20.

MISSOURI

Prepayment Medical and Surgical Care.—Medical, surgical, obstetric and fracture care of hospital patients will be included in a recently approved prepayment medical and surgical care plan of the Missouri State Medical Association. A committee was named by the association to launch the plan immediately and consists of Drs. Carl F. Vohs, St. Louis, chairman; Ira H. Lockwood, Kansas City; Marcus Pinson Neal, Columbia; Howard B. Goodrich, Hannibal, and Frank L. Feierabend, Kansas City. The new program will be known as the Missouri Medical Service, Inc., and will be operated on a straight cash indemnity basis and will not interfere with the physician's normal fee. According to the state medical journal the policy is to state that the indemnification amount will not in any way relate to the physician's fee and the amount paid will be considered by the patient as a part payment of the fee. The plan is to be available to all residents of the state, and every physician will have opportunity to cooperate.

NEW YORK

New Division of Product Development at Winthrop.—The establishment of a division of product development at Winthrop Chemical Company has been announced by Dr. Theodore G. Klumpp, president. The division, with headquarters at the company's plant at Rensselaer, will explore the postwar commercial potentialities of products now being supplied by Winthrop to the armed forces as well as new products developed in the company's laboratories.

Hospital News.—The Northern Westchester Hospital, Mount Kisco, has received \$50,000 from the Reader's Digest Association for the construction and equipment of a new emergency department and board and conference rooms on the first floor of the new south wing of the hospital, which is planned under a \$500,000 building program. Mr. and Mrs. Carl Tucker have subscribed more than \$31,000 to build and equip a new pediatrics department to occupy the first floor of an addition on the present northeast wing of the hospital. Mr. Tucker is president of the hospital and general chairman of the campaign committee.

Dental Examinations Start in Caries-Fluorine Demonstration.—The New York State Department of Health recently began the dental examinations of school children in the city of Newburgh, which, with the city of Kingston, is collaborating in a long range demonstration to determine the practicability of mass protection against dental caries by adding fluoride to public drinking water supplies. These communities were selected as study and control areas, respectively,

after careful consideration of many sections of the state which might be suited to such a demonstration (*THE JOURNAL*, May 6, p. 73). Dental inspections of about 1,000 children in various age groups of 5 to 14 years will be made. The purpose is to obtain, at the outset of the demonstration, a dental caries index which will serve as a basis for comparison with the terminal figures at the end of ten years, the length of time which must elapse before the full benefits of the water treatment are realized. According to *Health News* it is also planned to make a pediatric investigation of a representative sample of the child population, including a general physical examination, urinalysis and x-ray films of the long bones and centers of ossification. Procedures for these examinations are now being prepared, and when they are completed a substantial portion of the child population will be examined. All examinations will be made before the fluoride is added to the water supply.

New York City

Floating Hospital Opens Season.—On July 3 the St. John's Guild floating hospital, the *Lloyd I. Seaman*, began its first seasonal excursion up the Hudson carrying physically handicapped children and their mothers. The excursions will continue daily except Sunday until September 2. The excursions are financed by about 330 organizations. The trained staff on the floating hospital includes two physicians and a dentist, four registered nurses and five practical nurses. Physically handicapped children and those with heart disease comprise the patients.

New Bureau of Medical Education.—The New York Academy of Medicine has created a bureau of medical education to serve all physicians interested in furthering their medical education, but particularly the physicians returning from war and the increasing number of foreign physicians who arrive in New York for postgraduate instruction and training. The bureau, organized by and operated under the supervision of the committee on medical education of the New York Academy of Medicine, will render its services without charge. It plans to publish announcements of postgraduate medical courses conducted by the universities and the hospitals of New York City. Thirty-three of the leading hospitals have been invited to collaborate in this work. A group of advisers representing the special fields of medical practice has been appointed to supervise the work of the bureau.

Changes at Long Island College of Medicine.—Dr. William Dock, professor of medicine at the University of Southern California School of Medicine, Los Angeles, has been appointed to a similar position and head of the department at the Long Island College of Medicine, Brooklyn. This is the first time in the eighty-three years history of the college that it has had a full time professor of medicine. Edward Muntwyler, Ph.D., professor of experimental biochemistry, Western Reserve University School of Medicine, Cleveland, has been appointed professor and executive officer of the department of biochemistry, at Long Island and James B. Hamilton, Ph.D., associate professor of anatomy, University of Missouri School of Medicine, Columbia, professor and executive officer of the department of anatomy. These appointments fill the vacancies that occur with the retirement of Dr. Tasker Howard, professor and executive officer of the department of medicine; Edgar D. Congdon, Ph.D., professor and executive officer of the department of anatomy, and Matthew Steel, Ph.D., professor and head of the department of biochemistry. Dr. Howard has been connected with the school since 1910, Dr. Congdon since 1932 and Dr. Steel since 1914. Dr. Fred L. Moore, who for the past two years has been director of the division of public health studies of the Commonwealth Fund, has been appointed to a newly created post as professor of social and environmental medicine in the department of preventive medicine and community health at the medical school. Before joining the Commonwealth Fund, Dr. Moore had held a professorship in the department of preventive medicine and community health. In his new capacity he will also serve as medical director of the Polhemus Clinic of the Long Island College Hospital, in charge of the outpatient department of the hospital. Other changes on the faculty effective July 1 include:

Dr. Elberton J. Tiffany promoted to associate professor of the department of bacteriology.

Dr. Francis E. Mallon promoted to assistant clinical professor in the department of ophthalmology.

Drs. Charles A. Hargitt, Edwin Clifford Place and Michael J. Buonaguro newly appointed as assistant clinical professors in the department of surgery.

promoted to clinical professor in the department of surgery.

bro promoted to assistant clinical professor in the department of surgery.

NORTH CAROLINA

Poliomyelitis.—Serious outbreaks of infantile paralysis in western North Carolina have called out the emergency services of the National Foundation for Infantile Paralysis, which has announced it had advanced \$50,000 for epidemic relief and sent a staff of doctors, nurses and physical therapy technicians into the region. There were 264 cases of poliomyelitis reported in the state through July 10. Through the National Foundation, it was announced, doctors, nurses, physical therapists and supplies and equipment were sent from many parts of the country into the affected areas. It is almost miraculous, according to Dr. Don Gudakunst, how the people have worked in setting up emergency hospitals almost overnight. This was particularly true in Catawba County, where a score of cases were being reported daily and there were insufficient hospital facilities in the state to receive the case load. The National Foundation's state representative, Clarence H. Crabtree, immediately investigated the situation. He and Dr. A. Gaither Hahn, Catawba County chapter chairman of the National Foundation, suggested that the Lake Hickory Fresh Air Camp be converted into an emergency hospital. That same afternoon the children who were attending the camp were en route to their homes, and the camp facilities were made available. Dr. Hahn called Col. Frank Wilson at the Moore General Hospital at Black Mountain, a convalescent hospital for soldiers, who agreed to lend 40 beds. Working throughout the night Crabtree, Dr. Hahn and Dr. Harold C. Whims, local health officer, arranged for trucks to transport the beds, and carpenters were summoned to make the necessary alterations. Three days later the emergency hospital admitted its first patients. The cases continued to arrive, including one needing immediate treatment in a respirator, Dr. Gudakunst stated. Miss Beatrice Cobb, county chairman and head of the National Foundation's Women's Division in nearby Burke County, was told of the situation. Half an hour later the vitally needed respirator was in operation at the emergency hospital. Another patient required similar treatment. A call was placed to Gettys Guille, chairman of the National Foundation's Rowan County chapter, and a respirator was secured immediately. Since that time two more respirators have been sent into the area by the foundation from its Boston depot. The case load increased so rapidly that another appeal was made to Colonel Wilson for two army hospital tents. Additional beds were furnished, and electricians and carpenters worked half the night to set up the tent platforms and accessory equipment, the Nutton Bonous Lumber Company donating the lumber. The next morning 10 soldiers and 15 laborers, driven by a Wac, arrived at the camp and pitched in. The Wac promptly changed into coveralls, helped carry lumber, and aided in the construction of the tents. Dr. Gudakunst's report stated that army personnel remained at the camp a week, constructing ramps and other facilities. Meanwhile the Red Cross had recruited nurses, who were instructed in their special duties by two supervising nurses from the state health department. Kitchen and dining room plans were drawn up overnight by Q. E. Herman, a local contractor, who has earned the nickname of "kaiser" because he seems to do the impossible almost immediately. He set a crew of carpenters working day and night shifts, and four days later this part of the building was in use. Convicts from the state prison aided also. Several score helped clear the grounds and dug ditches for enlarged sewage disposal plants. The water company installed a 3 inch water main to the camp 3 miles from town and then turned over an old 1 inch line to the gas company for piping in gas. The telephone company speedily installed trunk lines and switchboard. Additional sheets were needed, and an order for fifty was placed with one store, which immediately sent one hundred without charge. The supply of children's cribs was exhausted, so carpenters built new ones as fast as they were called for. The Hickory Fire Department installed a 3 inch main overnight, stationed a chemical truck on the grounds and placed a twenty-four hour fire patrol on watch. Epidemiologists, working under research grants from the National Foundation for Infantile Paralysis, are in the stricken area searching for clues as to the manner of spread of the disease. Among the research investigators are Drs. Joseph Melnick, Robert Ward, Dorothy Horstmann, from Yale University, and Dr. Thomas Francis Jr. of the University of Michigan. Two others, Drs. Kenneth Maxcy and Howard Howe of Johns Hopkins University School of Medicine, Baltimore, will arrive shortly.

OHIO

Dr. Baker Retires as Chairman in Anatomy.—Rollo C. Baker, Ph.D., chairman on leave of the department of anatomy of the Ohio State University College of Medicine, Columbus, will retire at the close of the academic year. He will retain his position as acting dean of the college of medicine.

RHODE ISLAND

The Charles F. Gormly Fund.—At a meeting of the house of delegates of the Rhode Island Medical Society, May 18, authorization was given to the purchase of a number of books on legal medicine for the library of the society from funds designated the Charles F. Gormly Fund. Each book will carry a plate showing that it belongs to the Charles F. Gormly collection. The fund was created with the balance of money left from the commissioning of a portrait of Dr. Gormly hung in June 1943. Dr. Gormly was the immediate past president of the state medical society at the time of his death June 16, 1943. The portrait was executed to mark the years of service of Dr. Gormly to the state medical society, and the collection of books on legal medicine will serve to memorialize one of his main interests. While there is a possibility that friends of Dr. Gormly might in time contribute toward the fund to continue it, the present plans of the library committee are to purchase new books from time to time until the present fund is expended.

Department of Medical Sciences Created at Brown University.—A department of medical sciences has been created at Brown University, Providence, it was announced July 12. Drs. Charles A. McDonald and Alexander M. Burgess, associated with the division of university health for some time, have been appointed professors of health and hygiene in the new department, which hopes to perform a number of important functions within the university and in the relationships of the university to the medical profession and hospitals of the community. It was stated that the new department will assist the university in assuming a larger responsibility for the general education of its students in matters of health. It is designed in part to meet the needs and desires of recent graduates of medical schools whose postgraduate studies in certain specialized fields of medical science have been interrupted by war service. The announcement stated that the university plans to cooperate in the development of programs of postgraduate study and research for members of the resident staffs of the hospitals of the community.

WEST VIRGINIA

Society Offers Free Service in Care of Tornado Patients.—At a meeting in Clarksburg on July 7 the Harrison County Medical Society unanimously agreed that no charge is to be made for services rendered by members in connection with the tornado which swept through the Shinnston area on June 23, leaving a death total of 70 from that community alone and sending many injured persons to the hospitals. Members of the medical society waived not only fees for services at the time of the disaster but also fees for medical and surgical care that may be necessary until the injured have recovered. The society is composed of 85 physicians, 20 of whom are serving in the armed forces.

GENERAL

Basil O'Connor Head of Red Cross.—On July 13 President Roosevelt appointed Mr. Basil O'Connor, president of the National Foundation for Infantile Paralysis, New York, as chairman of the American Red Cross. George L. Harrison, LL.D., New York, had been serving as temporary chairman.

Outbreak of Infantile Paralysis.—On July 12 Kentucky reported 129 cases of poliomyelitis with 4 deaths, and medical authorities were said to be tightening regulations to keep the outbreak to a minimum. An Associated Press report stated that the count in other states was Mississippi 23, Georgia 9, Virginia 26, South Carolina 16, Louisiana 68, Alabama 9 and Florida 13.

Pediatric Examinations.—The American Board of Pediatrics announces that a written examination for all applicants expecting to take the spring oral examinations will be held March 2, 1945. Oral examinations will be held in New York on April 14 or 15, 1945, applications to be in by Dec. 15, 1944, and Chicago, May 19 or 20, 1945, applications to be in by Jan. 19, 1945. Dr. C. Anderson Aldrich, 115½ First Avenue S.W., Rochester, Minn., is the secretary of the American Board of Pediatrics.

Fourth of July Accidents.—Deaths occurring during the recent Fourth of July week end totaled 447, according to the Associated Press. It was stated that although the death list totaled less than half of that expected by the National Safety Council the fatalities recorded were nearly 150 more than last

year, when 298 were reported for the three day week end. Traffic mortalities led the list, with 177 counted in thirty-eight states and the District of Columbia. Thirty-seven accidental deaths occurred in California, with 22 traffic fatalities. Drownings accounted for 142 lives. No deaths were reported caused by fireworks.

Commonwealth Fund Merges Health Studies and Public Health.—The Commonwealth Fund, New York, has merged its division of health studies with the division of public health. Miss C. R. Randolph in the division of health studies has been named director of studies. Dr. Clarence L. Scanlin is director of the division of public health and Dr. Harry E. Handley assistant director. Dr. Fred L. Moore recently resigned as director of the division of health studies of the Commonwealth Fund to assume a newly created position of professor of social and environmental medicine in the department of preventive medicine and community health at Long Island College of Medicine, Brooklyn (this issue, p. 859).

Smoke Association Creates Section on Health Aspects of Smoke.—The Smoke Prevention Association of America at a meeting on June 6 in Detroit passed a resolution calling for the creation of a section on the health aspects of the smoke nuisances to collect data and study the subject with a view to recommending necessary measures for the abatement of the smoke evil in the interest of the health of the people. The resolution was introduced by Dr. Emil Amberg, Detroit, chairman of the smoke abatement committee of the Wayne County Medical Society. Mr. Frank A. Chamber, 139 North Clark Street, Chicago, is the secretary-treasurer of the Smoke Prevention Association of America.

LATIN AMERICA

Health Activities in Latin America.—*New Institute of Hygiene.*—On May 15 the Institute of Hygiene, Havana, Cuba, was formally opened in new headquarters. The buildings were recently occupied by the headquarters of the police but have been renovated to accommodate the institute. There is a division concerned with clinical diagnostic procedures, including parasitology, hematology, serology and bacteriology; a division concerned with sanitary, chemical and physical examinations of water, sewage, swimming pools, food and drugs, and a division for the manufacture of vaccines, plasma, serums and the like to supply the public hospitals and dispensaries of Cuba. A close relationship will be developed with the Hospital for Infectious Diseases. The institute will have a staff of about 150 persons, including 10 physicians and 1 sanitary engineer. Dr. Moises Chediak is director of the institute, which will be under the direction of a board of seven trustees appointed by the president. Until two years ago the institute was a part of the Carlos Finlay Institute, which will continue the functions of teaching and research. A feature of the dedication was the presentation of decorations by the Cuban government to the Rockefeller Foundation and the American Public Health Association and the posthumous award to the American Yellow Fever Commission in honor of great services rendered to yellow fever control.

Distribution of Doctors.—The committee on education of the Puerto Rico Medical Association has completed a survey which shows that there are not enough physicians available for the needs of the people. While the proportion of doctors revealed in the survey is the most favorable yet registered, it is believed that services are inadequate for rural sections. The report recommends that an effort be made to reorganize the staffs of the health units in order to distribute these physicians better. The report adds that the establishment of a medical school, the provision of scholarships for Puerto Rican students in other universities and the reorganization of municipal health and welfare boards would better stabilize the proportion of physicians to the civilian population.

Activities of Chest Physicians.—The American College of Chest Physicians announces that an Argentine chapter has been organized with Dr. Gumersindo Sayago, Cordoba, as president, Dr. Raúl F. Vaccarezza, Buenos Aires, vice president and Juan Carlos Rey, Buenos Aires, secretary-treasurer. Plans are under way to organize a chapter in Peru.

Tuberculosis Award Goes to René Mendoza.—Dr. René García Mendoza Rabell, Havana, was recently presented with the Joaquín Martos Award for the best work presented on a tuberculosis subject. The prize was instituted by the National Council of Tuberculosis of Cuba in memory of the late Dr. Joaquín Martos.

Control Boards for Penicillin.—The various Latin American governments are cooperating in the distribution of penicillin by setting up control boards similar to those in the United States.

LONDON

(From Our Regular Correspondent)

June 17, 1944.

Plans for the Control of Narcotic Drugs in Liberated Europe

The Permanent Central Opium Board has issued a report stating that it has reason to believe that the military and civil authorities concerned are giving attention to the urgent question of restoring complete control over narcotic drugs in enemy occupied countries as soon as these are liberated. It will be for the military authorities, acting no doubt in arrangement with experienced civil drug control officials, to carry recommendations into effect. Unless control can be effected, the board considers that there will be grave danger of a recrudescence of illicit traffic similar to that which occurred after the last war, with consequent addiction among the suffering people. They think that in some cases there will be three stages for which provision may be necessary: (1) during the period of military control, (2) the period of reestablishment of national administration, with allied occupation and supervision, and (3) the initial period of full national control. During the first stage all drugs in civilian hands should be reported and placed under control of the designated authority. No imports should be allowed for civilian use, by relief organizations or otherwise, except under a license. Civilian supplies should be allowed solely on medical prescriptions, and periodic returns should be made by relief organizations and firms. Any factory manufacturing drugs should be placed under control, and no new one should be allowed to start production except under license. No imports of raw materials—opium, poppy straw, crude morphine, coca leaves, crude cocaine or Indian hemp—should be allowed except under license.

Control in the second and third stages should develop out of the measures taken during military occupation and lead to the full system of national and international control established under the conventions of 1925 and 1931. There are already indications that the illicit trafficker is very much alive. Sufferers from the war will in many cases succumb if the temptation is presented to them.

Shortage of Bodies for Dissection

There is at present a shortage here of human bodies for dissection. In a lecture delivered at the Royal College of Surgeons Dr. Neville Goodman, government inspector of anatomy, reviewed the situation since 1832, when the anatomy act was passed. This put an end to body snatching by empowering persons having lawful custody of a body to allow it to be dissected. But this power is overridden if the deceased expressed in writing or in the presence of two persons his wish not to be dissected, or if his relatives object. The greater part of the supplies for dissection are the unclaimed bodies of persons who have died in institutions. In 1941 and 1942 these were 97 per cent of all bodies available for dissection; the remaining 3 per cent were bequests by the deceased. The increased prosperity of the masses has led to a decline in the number of unclaimed bodies. The maximum number of students was formerly sixteen per body; two for each limb, four for the head and neck and four for the thorax and abdomen. The shortage of bodies has caused the number of students per body to be increased to twenty today.

As a remedy for the shortage, Dr. Goodman suggests that the number of bequests of bodies should be increased. He is convinced that if more was known by the medical profession and by the public of the need for bodies, and the conditions of disposal were explained, the proportion of bequests would rise

rapidly. The professor of anatomy who receives a body is responsible for its preservation until it is ready for burial, which is conducted by clergyman of the faith which the deceased professed. Government forms for persons intending to bequeath their bodies are supplied.

The Reform of Medical Education

As stated in a previous letter to THE JOURNAL, the reform of medical education is being widely discussed. In his opening address to the General Medical Council Sir Herbert Eason, the president, stated that in all the evidence they had submitted to the Departmental Committee on Curriculum and Examinations the council called attention to the poor standard of English attained by many students when they began their medical studies. The chief reason for this defect, he said, was premature specialization. As long ago as 1934 the Council reached the conclusion that the standard of general education for prospective medical students should at least be equal to that of entry into other learned professions and not below that of the matriculation examination of universities. In 1942 the council added that this education should be broad and not regarded as complete unless it included the general principles of physical and biologic science. Courses leading to the first M. B. examination should be taken at a medical school, the council held; this considered view was based on the fact that laboratory facilities at schools vary widely, few approaching university standard. Moreover, it was felt that teaching these subjects at other schools encouraged the student to enter on the medical curriculum at too early an age and to start specializing too soon.

In most communities, Sir Herbert stated, the physician has always been looked on as an educated man of the world whose opinions on problems other than medical carry weight. To maintain this position it is essential that the medical student shall have a high standard of general education and an outlook beyond the confines of an examination syllabus. For complete and adequate medical education, he said, it is essential that teachers of preclinical subjects work in close collaboration with the teachers of clinical subjects, so that not only will the former be able to impress on students the bearing of preclinical subjects on their clinical studies, but also clinical teachers shall have associated with them the teachers of purely scientific subjects in any investigations.

As regards the curriculum generally, the Council must always bear in mind that it was primarily for the general practitioner and that higher medical education is a matter for postgraduate instruction, the president said. But the study and teaching of social and preventive medicine deserve further encouragement, he added, so that students and physicians may be better acquainted with the influence of social, occupational, genetic and domestic factors on the incidence of disease and so that measures other than those usually employed in remedial medicine should be promoted for the protection of the individual and the community against such forces as interfere with the full development and maintenance of man's mental and physical capacity. It would be an advantage both to the community and to the practitioner, he felt, if the medical student who had passed his final examination was to spend some time in practice under supervision before embarking on his own account.

Industrial Medicine

The increased attention now being given to what is called here social medicine, of which industrial medicine may be regarded as a branch, is shown by the invitation of the Social and Preventive Committee of the Royal College of Physicians to representatives of the General Council of the Trades Union Congress to attend one of the committee meetings and state their views on the training for and practice of industrial medicine. In general, the Trades Union Council desires

the medical profession to recognize more fully the importance of provision for the study of industrial disease. It has suggested a specialized course of training to qualify young practitioners for industrial appointments. At the same time the Council sees a need for a more general diffusion of knowledge of industrial medicine, because the doctor in the factory may not be the worker's medical adviser, and a full time factory doctor certainly will not be. In the opinion of the Trades Council the treatment of occupational diseases is a distinct branch of medicine to which special attention should be given in medical practice as well as in the factory health code. With regard to the status of industrial medical practice, the Council would like to see established a public service that would make the factory doctor independent of the employer. The meeting and the discussion were informal and take their place in a comprehensive inquiry which the Royal College of Physicians is making.

BRAZIL

(From Our Regular Correspondent)

June 3, 1944.

Brazilian War Bread

Dr. Josue de Castro, director of the Division of Food of the Brazilian Office of the Coordinator of Economic Mobilization, has just published a technical paper explaining the scientific foundations of the so-called war bread in Brazil. He stresses the importance of bread as a fundamental food, and considering that wheat, the basic raw material for its production, is largely an imported product in Brazil, he points out that this problem has always occupied the attention of the authorities. The "War Bread Committee" in charge of the task of seeking a rational solution for the problem was set up in due course by the coordinator of economic mobilization. As a first step in this direction the average consumption of bread in Brazil had to be ascertained, and it was found to be very low in contrast to other large bread consuming countries, this being explained by Brazilian food habits and by economic difficulties in obtaining this commodity. Although bread is not a protective food, as are meat, milk, vegetables and fruits, the possibility of improving the Brazilian diet by wider and more rational use of bread was judged worth examining in order to justify the measures to encourage a higher consumption of such a food among the people. The next step was to study the nutritive value of the type of bread consumed in Brazil during the recent difficult years, which is composed of a mixture of 85 per cent wheat flour and 15 per cent manihot flour, the nutritive properties of which are inferior to those of pure wheat flour. Studies were then made of the measures adopted by the American, British and Canadian governments in the present emergency. The so-called enriched bread in use in the United States is inaccessible in practice to poorer nations. A solution for the problem was then sought through an increase of the extraction rate of wheat, in use in Great Britain and in Canada, to obtain the maximum nutritive value from whole wheat. Research in this direction, in both Brazil and Argentina, was aimed at (1) a comparative study of the nutritive value of flour of different extractions, (2) the digestibility of the various types of bread prepared with these flours and (3) the perishability of the several types of flour. These investigations revealed that flour at 85 per cent extraction had the highest amount of nutritive elements, though it was inferior as to perishability. Nevertheless, these results decided the committee to recommend the use in Brazil of baking flour of 85 per cent extraction. This measure enables production to be increased by about 10 per cent for the same amount of wheat imported, at the same time producing a type of bread with much higher nutritive value than that heretofore in use.

The Death of Dr. Moncorvo Filho

Dr. Arthur Moncorvo Filho, one of the pioneers of pediatrics and infant hygiene in Brazil, died a few days ago at the age of 73. Dr. Carlos Moncorvo, his father, graduated in medicine in 1874 and was a pioneer in pediatrics in Brazil. He was a leading member of the National Academy of Medicine of Rio de Janeiro and a leading pediatrician of the city, in which he practiced until his death in 1899. Moncorvo Filho, who was an active collaborator with his father in establishing pediatrics as an independent branch of medicine in Brazil, in 1901 founded the Instituto de Proteção à Infancia (a child welfare institute), with a large infant clinic, and created a national foundation, with branches in several states of Brazil, to give specialized medical care to infants and to promote the health of the child, thus anticipating by many years the efforts of the public administration in behalf of child welfare. As a pediatrician he succeeded in having a large practice in Rio de Janeiro, but he has been particularly noted as the benefactor of many thousands of poor children cared for and assisted freely at his well known infant clinic. For some time the Instituto Moncorvo, as the institution was known, acted as an important educational center for many young physicians who intended to specialize in pediatrics. In 1941 the city administration bought the Instituto Moncorvo from its founder, in recognition of the good work done by him in the field of child welfare. Since then the building has been enlarged and refitted as a hospital and is now known as the Moncorvo Filho Hospital. During his life Dr. Moncorvo Filho published several books and many papers dealing with pediatrics and child welfare.

Brief Items

Dr. J. P. Fontencelle, professor of public health administration in the course of public health of the Oswaldo Cruz Institute, has been appointed director of the division of health information in the Rio de Janeiro city department of health.

Two new divisions have been created in the biologic laboratory of the medical department of the Brazilian army, one to produce therapeutic serums and the other to operate a blood bank. The building to accommodate these new divisions has recently been opened. It bears the name of the late Dr. Ismael da Rocha, who was a leading army physician and one of the most efficient among the past heads of the army medical department. The division of therapeutic serums and the blood bank will be directed by two army physicians, Major José F. Rodrigues and Capt. Flavio P. Mesquita.

Dr. Raul David de Sanson, a noted specialist practicing in this city, has been appointed professor of otorhinolaryngology at the Medical School of the University of Rio de Janeiro.

Marriages

JOHN J. MARLOWE, East Chicago, Ind., to DR. ROMONA A. MENZIE of Chicago, Aug. 22, 1943.

THOMAS LYNCH MURPHY to Miss Virginia B. McKenzie, both of Salisbury, N. C., June 10.

GEORGE K. STRODE, New York, to Mrs. Josephine Clark Dillard of Perry, Mo., June 29.

JOHN R. HOWARD, Vultee Field, Calif., to Miss Lucile V. Jarvis at La Salle, Ill., April 6.

WILLIAM HOLMAN DAUBS, Foreman, Ark., to Mrs. D. E. Nichols of Texarkana, May 9.

HAROLD KATZMAN, Utica, N. Y., to Miss Frances Somnecorn of Miami Beach, Fla., June 4.

SAMUEL C. DE LAURA, Norfolk, Va., to Miss Margaret Kapp of Durham, N. C., June 1.

RICHARD H. BERG to Miss Edith Teak, both of Oxford, Mich., June 10.

GEORGE F. REED, Cohoes, N. Y., to Miss Marion Lee of Troy recently.

Deaths

Samuel Iglauer * Cincinnati, Medical College of Ohio, Cincinnati, 1898, professor of otolaryngology at the University of Cincinnati College of Medicine, specialist certified by the American Board of Otolaryngology and the American Board of Plastic Surgery, secretary, Section on Laryngology, Otolaryngology and Rhinology from 1922 to 1925 and chairman, 1925-1926, American Medical Association, member of the American Academy of Ophthalmology and Otolaryngology and second vice president in 1935, member of the American Laryngological, Rhinological and Otolaryngological Society and formerly a member of the council, member and in 1923 president of the American Broncho-Esophagological Association, in 1933 president of the Cincinnati Academy of Medicine, member of the American Laryngological Association, Cincinnati Otolaryngologic Society and the American Association for the Advancement of Science, member of the board of directors since 1925 of the Cincinnati Anti-Tuberculosis League, fellow of the American College of Surgeons, in 1913 member of the city charter commission, member of the medical advisory board number 1, Selective Service, a captain in the medical corps of the U S Army, 1918-1919, director, otolaryngology, Children's Hospital, Cincinnati General Hospital and the Jewish Hospital, where he died suddenly June 23, aged 72, of cerebral hemorrhage.

William Andrew Krieger * Poughkeepsie, N. Y., Albany Medical College, 1906, specialist certified by the American Board of Otolaryngology, member of the House of Delegates of the American Medical Association in 1942, member of the American Academy of Ophthalmology and Otolaryngology and formerly vice president, member of the Association for Research in Ophthalmology, Inc., fellow of the American College of Surgeons and the New York Academy of Medicine, past president of the Dutchess-Putnam Counties Medical Society, in 1942 vice president of the Medical Society of the State of New York, served during World War I, consulting ophthalmologist and otolaryngologist, Vassar Brothers, Hudson River State and Bowne Memorial hospitals in Poughkeepsie, Harlem Valley State Hospital, Wingdale, Matteawan State Hospital, Beacon, Butterworth Memorial Hospital, Cold Spring, Sharon Hospital, Sharon, Conn., and the Wassau State School, Wassau, director and president of the Merchants' National Bank and Trust Company, died May 19, aged 61, of arteriosclerotic heart disease.

Edward Huntington Williams * Santa Monica, Calif., State University of Iowa College of Medicine, Iowa City, 1892, formerly demonstrator of histology at his alma mater, at one time assistant physician at the Matteawan State Hospital, Beacon, N. Y., and the Manhattan State Hospital, New York, served on the staffs of the Los Angeles General Hospital and five sanatoriums, associate editor of the tenth edition of the Encyclopedia Britannica, published in England, and the United Editors' Encyclopedia, joint author, with Dr. Henry Smith Williams, of a five volume history of science, an eleven volume series called "Every Day Science" and "The Wonders of Science in Modern Life," in ten volumes, author of "The Walled City," "The Question of Alcohol," "Opiate Addiction—Its Handling and Treatment," "Our Fear Complexes," "The Doctor in Court," "Insanity Plea," "Animal Autobiographies" and others, died June 24, aged 75, of heart disease.

Leonard Wheeler Ely, Palo Alto, Calif., College of Physicians and Surgeons, New York, 1895, at one time practiced in New York and Denver, member of the California Medical Association, chairman of the Section on Orthopedic Surgery, American Medical Association, 1913-1914, from 1913 to 1924 associate professor of surgery (orthopedics) at the Stanford University School of Medicine, where he had been professor of surgery (orthopedics) from 1924 to 1934 when he became professor of surgery (orthopedics) emeritus, captain, medical corps, U S Army, during World War I, formerly associated with the U S Public Health Service, served on the staffs of the Orthopedic and Presbyterian hospitals in New York, on the staff of the Stanford Hospital, San Francisco, author of "Joint Tuberculosis," "Bone and Joint Diseases" and "Inflammation in Bones and Joints," died June 17, aged 75, of coronary thrombosis.

Frank Patrick McNamara * Dubuque, Iowa, Harvard Medical School, Boston, 1918, specialist certified by the American Board of Pathology, Inc., past president of the Iowa State Medical Society and the Dubuque County Medical Society, member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists, fellow of the American College of Physicians, at

one time instructor in pathology at the Yale University School of Medicine, New Haven, Conn., served on the staff of the Decorah Hospital, Decorah, on the staffs of St. Joseph Mercy and Finley hospitals; in 1933 he received the silver medal from the Scientific Exhibit of the American Medical Association for an exhibit illustrating the activities of the pathologic laboratory in a hundred bed hospital, died July 2, aged 59.

Elmer Isadore Huppert * New York, University and Bellevue Hospital Medical College, New York, 1903, assistant clinical professor of surgery at his alma mater, now known as the New York University College of Medicine, member of the American Proctologic Society, fellow of the American College of Surgeons, assistant attending surgeon third division, Bellevue Hospital, consulting proctologist, Long Beach Hospital, Long Beach, N. Y., St. John's Long Island City Hospital, Long Island City, Lutheran and Wickersham hospitals, died in the Doctors Hospital June 30, aged 64.

Ruby Lacey Cunningham * Berkeley, Calif., University of California Medical School, San Francisco, 1914, formerly instructor in medicine at her alma mater and assistant professor of hygiene and assistant physician to women in the students' health service, senior physician in the dispensary of the Ernest V. Cowell Memorial Hospital, past president of the Pacific Coast Section and a member and formerly vice president of the American Student Health Association, served as president of the Berkeley Health Center, died June 2, aged 64, of cerebral hemorrhage.

George Winston Acker, Port Gibson, Miss., Medical College of Alabama, Mobile, 1889, secretary of the Claiborne County Medical Society, of which he had been past president, served as county health officer and county registrar, returned of the Spanish-American War, died in a sanatorium at Vicksburg May 13, aged 77, of carcinoma of the rectum.

Walter Gladwin Allison, Hope, Ark., Louisville and Portland Medical College, Louisville, 1908, member of the Arkansas Medical Society, shot and killed May 24, aged 74.

Ernest Houston Baird * Dyersburg, Tenn., Homeopathic Medical College of Missouri, St. Louis, 1903, past president and secretary of the Dyer-Lake-Crockett Counties Medical Society, past president of the West Tennessee Medical Society, councilor of the Ninth District of the Tennessee State Medical Association, on the staff of the Baird Brewer General Hospital; died May 14, aged 64, of coronary occlusion.

Charles G. Blackweider, New Springfield, Ohio, University of Maryland School of Medicine, Baltimore, 1895, for many years township physician, served on the staffs of hospitals in Youngstown, died in Cuyahoga Falls May 18, aged 75, of cerebral sclerosis.

Felix Anthony Blanchard * Bishopville, S. C., Tulane University of Louisiana School of Medicine, New Orleans 1921, died May 3, aged 46, of heart disease.

Bruce Tucker Bowens, Springfield, Mass., Tufts College Medical School, Boston, 1898, died March 13, aged 75.

John N. Bradley, Schenectady, N. Y., Albany (N. Y.) Medical College, 1875, died April 30, aged 91, of senility.

Julian Holt Buff, Orlando, Fla., Emory University School of Medicine, Atlanta, 1916, member of the Florida Medical Association, on the staff of the Orange General Hospital formerly on the staff of the Grady Hospital Atlanta, died May 10, aged 52, of heart disease.

John Blair Cross, Harriman, Tenn., Southern Medical College, Atlanta, 1896, for two terms a representative from Roane County in the state legislature formerly city health officer, served during World War I, died April 15, aged 75.

Peter James Fagan, New York, Albany (N. Y.) Medical College, 1892, died April 1, aged 73.

Robert Furman, New York, Albany (N. Y.) Medical College, 1889, served on the staffs of Broome Street Dispensary, New York Polyclinic and Roosevelt hospitals, surgeon for the Illinois Central Railroad, died March 13, aged 81.

William H. Furman, Henderson, N. C., Jefferson Medical College of Philadelphia, 1910, member of the Medical Society of the State of North Carolina, died April 3, aged 59.

Prince S. Gathings, Lawton, Okla., Meharry Medical College, Nashville, Tenn., 1906, died March 11, aged 64, of heart disease.

Charles Sebert Hale, Cisco, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1890, member of the State Medical Association of Texas; president of the chamber of commerce and the Lions Club, died March 22, aged 74, of pneumonia.

Harmon Lamontte Stanton @ Evansville, Ind.: State University of Iowa College of Medicine, Iowa City, 1920; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Vanderburgh County Medical Society; president of the board of health; on the staffs of the Deaconess and St. Mary's hospitals; died April 23, aged 50, of cerebral hemorrhage.

Frank Stradling @ Earlville, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1900; died suddenly in Hamilton May 1, aged 69, of heart disease.

James Page Strong, Kennedyville, Md.: Maryland Medical College, Baltimore, 1907; formerly associate professor of gynecology at his alma mater; at one time on the staff of the Maryland General Hospital, Baltimore; died April 20, aged 73, of heart disease.

Marshall S. Surensen, Viroqua, Wis.: Rush Medical College, Chicago, 1894; died in the Lutheran Hospital, La Crosse, March 27, aged 72, of strangulated hernia, peritonitis and myocardial failure.

John Lincoln Taylor @ Libertyville, Ill.; Rush Medical College, Chicago, 1894; also a pharmacist, since 1900 coroner of Lake County; past president of the Lake County Medical Society; served on the district appeal board during World War I; on the staff of the Victory Memorial Hospital, Waukegan; one of the founders and on the staff of the Condell Memorial Hospital; died May 5, aged 78, of coronary occlusion.

William Lawrence Taylor, Holdenville, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1910; member of the Oklahoma State Medical Association; for many years president of the Hughes County Medical Society; at one time official state physician at every execution at the state penitentiary in McAlester; died in the Wesley Hospital, Oklahoma City, April 16, aged 65, of uremia.

LT. (JG) TIFFANY V. MANNING
(MC), U.S.N.R., 1913-1944

**Frank Scott Tut-
hill**, Concord, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1891; member of the Michigan State Medical Society; president of the Farmers State Bank; died April 18, aged 77, of heart disease.

Thomas Poage Hunt Twaddell, Wynnewood, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; member of the board of health; served on the staffs of the Children's Hospital and Hospital of the University of Pennsylvania, Philadelphia, where he died April 12, aged 72, of pneumonia.

Lisby Lucius Wade @ Ryan, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1917; secretary of the Jefferson County Medical Society; at one time a school teacher; first county superintendent of schools; died in Waurika April 1, aged 62, of myocarditis.

Edgar S. Walford, Detroit; College of Physicians and Surgeons of Chicago, 1889; died May 6, aged 79, of bronchopneumonia.

James Ellsworth Webb, Mount Angel, Ore.; Willamette University Medical Department, Salem, 1898; served as mayor for many years; died April 23, aged 71, of carcinoma of the prostate with metastases.

Horace G. Welsh, Hutchinson, Kan.; Jefferson Medical College of Philadelphia, 1880; honorary member of the Kansas Medical Society; died March 9, aged 88, of carcinoma of the stomach.

Mark Hunking Wentworth, Concord, Mass.; Harvard Medical School, Boston, 1905; member of the Massachusetts Medical Society, American Psychiatric Association, New England Society of Psychiatry and the American Psychopathological Association; member of the staff of the Boston City Hospital; died May 15, aged 65, of pulmonary tuberculosis.

Elmer George Wherry, Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; member of the Medical Society of New Jersey; medical director of the Babies' Hospital-Coit Memorial; served on the staffs of the Newark Memorial Hospital, Hospital of St. Barnabas and for Women and Children and the Newark Eye and Ear Infirmary; died in the Presbyterian Hospital June 24, aged 74.

John Calhoun White @ Hazlehurst, Miss.; Chicago College of Medicine and Surgery, 1912; also a pharmacist; died May 22, aged 58, of heart disease.

Willard Francis Whitmarsh, Bridgewater, Mass.; Harvard Medical School, Boston, 1891; member of the Massachusetts Medical Society; died May 15, aged 79, of injuries received from a fall.

Charles A. Wiest, Stover, Mo.; University of Maryland School of Medicine, Baltimore, 1897; member of the Selective Service System; for many years county physician; died April 20, aged 70, of heart disease.

Charles Frederick Wilson, St. Louis; St. Louis College of Physicians and Surgeons, 1893; Harvard Medical School, Boston, 1898; died April 9, aged 76, of lobar pneumonia.

George Edgar Winslow @ Boston; Harvard Medical School, Boston, 1901; chairman of the local draft board number 34; examining physician for the Boston City schools and for industrial plants in Hyde Park; for many years associate member of the staff, Norwood Hospital, Norwood, Mass.; died April 17, aged 67, of carcinoma.

MAJOR WILLIAM REEMTSMA, U. S. A.
(NATIONAL GUARD), 1901-1943

Earle Cerenius Winsor, Schenectady, N. Y.; Syracuse University College of Medicine, 1917; member of the Medical Society of the State of New York; served during World War I; a charter member of the Schenectady Rotary Club; on the staff of the Aurclia Osborn Fox Memorial Hospital, Oneonta, where he died April 4, aged 53, of leukemia.

Franklin Crane Woodruff, Atlantic Highlands, N. J.; New York Homeopathic Medical College and Hospital, New York, 1887; died May 4, aged 78, of arteriosclerosis.

Ezekiel R. Young, Charco, Texas (licensed by years of practice); president of the school board; died April 21, aged 81, of angina pectoris.

KILLED IN ACTION

Tiffany Vincent Manning, Glen Cove, N. Y.; Long Island College of Medicine, Brooklyn, 1943; served an internship at the Meadowbrook Hospital, Hempstead; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Oct. 12, 1943; killed in action in the North Atlantic area April 28, aged 30.

William Reemtsma, New Braunfels, Texas; Baylor University College of Medicine, Dallas, 1933; formerly secretary of the Comal County Medical Society; served as health officer of Comal County; commissioned a captain in the U. S. Army (National Guard) on Nov. 25, 1940; later promoted to major; killed in action in North African area Nov. 29, 1943, aged 42.

Correspondence

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Dr. Caldwell's Laxative Senna Combined with Syrup Pepsin.—In April 1943 Dr. W. B. Caldwell, Inc., Monticello, Ill., and Sherman & Marquette, Inc., Chicago, which handles its advertising, stipulated with the Federal Trade Commission that they would cease representing that any therapeutic properties that the product may possess are enhanced by its pepsin content. They further agreed to discontinue any advertising which failed to reveal that the preparation should not be used when abdominal pain, nausea or other symptoms of appendicitis are present, provided, however, that such advertising need only contain the statement, "Caution: Use only as directed" when the labeling directions include a warning to the same effect. In this connection it is interesting to note that in 1939 the Commission had ordered the Caldwell concern to cease certain misrepresentations as to the efficacy of its product, then known under the various names "Syrup Pepsin," "Syrup of Pepsin" and "Dr. Caldwell's Syrup Pepsin." The order prohibited use of the word "pepsin," alone or in association with other words, to describe a preparation not containing sufficient pepsin as an active ingredient to possess substantial therapeutic value because of the pepsin content. The order intimated that the action of the Caldwell preparation depended chiefly on the presence of senna and cascara sagrada.

FaSet.—This device is put out by L. G. Carter and R. B. Kalbach, trading as FaSet Company, Rockville Centre, Long Island, N. Y. In June 1943 these persons and Henry Haas and Adrian Bauer, trading as Adrian Bauer Advertising Agency, Philadelphia, stipulated with the Federal Trade Commission to discontinue the following advertising misrepresentations: That the device is a "face lift" or a "new tissue form" or that its use imparts firmness or beauty to the face or neck, lifts, rebuilds or strengthens the muscle tissues, or removes double chin or face lines.

Formula 301 and Formula 301A.—These are put out by the Kay Preparations Company, Inc., of New York, which stipulated with the Federal Trade Commission in May 1943 to discontinue the following advertising misrepresentations: That Formula 301 is not a cosmetic, but a scientific discovery for the correction of beauty imperfections such as acne, pimples, enlarged pores, oiliness or skin eruptions, whether due to surface skin disorders or systemic causes, that it acts "fast" or, in fact, is at all effective under the make up to clear the skin of imperfections, that "no matter how bad your face may look now," amazing results will follow within two weeks by using the preparation, and that in 1 to 5 days, or within any specified time, it banishes skin imperfections. With regard to Formula 301A, the concern stipulated that it would cease representing that this is a "Pure Sulphur" soap, or more effective than any other standard facial soap in preventing rancidity of oil or eruption in the skin. Further, the concern stipulated that it would discontinue use of the term "dermatician" as applied to a cosmetician who is not a dermatologist, and the words "Special Sulphur" as part of the trade designation of Formula 301A.

Kovac, Chikovac, Papaya Dylestin and Kovac Type Acidophilus Culture.—In May 1943 the Kovac Laboratories, Inc., Los Angeles, entered into a stipulation with the Federal Trade Commission to discontinue the following advertising misrepresentations, among others, concerning these products: That any of them is capable of bringing about good appetite, good digestion, vitality, strong fighting blood, sound nerves, refreshing sleep or efficient body resistance against disease; that by their use old age or body deterioration can be deferred or corrected, or that because of their acidophilus content, or otherwise, the Kovac preparations constitute effective treatments for neuralgia, asthma, bronchitis, high blood pressure and some other disorders. The concern further agreed to cease naming mineral salts or other chemical elements as ingredients of its products, which references might suggest that such content has any potency or significance in producing and sustaining healthy blood, glands, nerves or other fluids, plasma or tissues of the body, when, in fact, such ingredients are not present in amounts sufficient to have any appreciable effect for the purposes designated.

Seal-Cote.—That this lacquer will cause nails to grow longer, will aid their natural growth, or correct or prevent their splitting or breaking, were advertising misrepresentations which the Flamingo Sales Company of Hollywood, Calif., agreed to discontinue, in a stipulation that it entered into with the Federal Trade Commission in June 1943. The stipulation also was signed by Bernard Weinberg, trading as Milton Weinberg Advertising Company, Los Angeles, who prepared the advertising copy.

PENTOTHAL SODIUM SLOUGH

To the Editor.—In discussing the results of their experiments on the prevention of pentothal sodium slough by procaine hydrochloride, Elder and Harrison (*THE JOURNAL*, May 13, p. 116) suggest that the beneficial action of the procaine may be due to its prevention of local vasospasm.

I should like to call attention to some related observations reported by A. D. Speransky, director of the Department of Pathophysiology of the All-Union Institute of Experimental Medicine and published in English translation in 1935 (*A Basis for the Theory of Medicine*, Moscow, Inra Cooperative Publishing Society, 1935, p. 163). In a large number of experiments in dogs he was able to demonstrate the production of ulcers of the extremities after the application of irritating substances to the central end of the severed sciatic nerve. He also reported some successful attempts at the treatment of trophic ulcers in human beings by procaine block. These experiments were part of a much larger project in which the role of the central nervous system in the pathogenesis of organic disease was investigated in detail and many rather surprising experimental results were obtained.

I hope that this communication may stimulate further interest in repeating and either confirming or disproving the results of the Russian author. They are certainly too important to be neglected.

ARTHUR SHAPIRO, M.D., Brooklyn

To the Editor.—In the May 13 issue of *THE JOURNAL* is an article by Elder and Harrison on the prevention of pentothal sodium slough with procaine hydrochloride. They stated that there had been no opportunity to test the method in man, and the suggestion is made that the method might be useful in preventing slough caused by the extravascular injection of other irritants.

In 1931 I was privileged to spend several weeks with the late Dr. Soma Weiss, who at that time was at the Thorndike Memorial of the Boston City Hospital. He was working with Dr. George Robb and Dr. Lawrence Ellis on the sodium cyanide circulation time. As an experimental subject I was given an injection of sodium cyanide solution, which through accident was deposited outside the vein. Dr. Weiss immediately injected 1 per cent procaine hydrochloride solution, which gave prompt relief from the intense pain. No slough appeared, although sodium cyanide solution is decidedly alkaline.

Since that time I have had the occasion to use and to show other physicians Dr. Weiss's effective method in both controlling pain and preventing slough following the accidental extravascular injections of irritating agents, in particular the arsenicals and mercurial diuretics.

MILTON KISSIN, Major, M. C., A. U. S.

To the Editor.—In *THE JOURNAL*, May 13, page 117, Elder and Harrison suggest the "possibility . . . of procaine in preventing tissue necrosis . . . in other solutions that are accidentally extravasated during intravenous medications, e.g., arsenical compounds. . . ." In *Queries and Minor Notes* in *THE JOURNAL*, Jan. 28, 1939, "M.D., Connecticut" asked how to relieve the patient who suffered from neosarsphenamine leaking into the tissues during an intravenous injection. I began using concentrated solutions of neosarsphenamine over twenty-five years ago and called attention to their use in the December 1913 issue of the *California State Journal of Medicine*. On more than one occasion I too, "owing to the patient's restlessness" or to mine (!) or to movements associated with release of tourniquets and the like have noted leaks into the tissues. Occasionally the patient remains silent. As a rule

patients at once complain of pain. With the slightest leak, even if the patient has not noticed it, it has been my custom immediately to inject 1 per cent solution of procaine hydrochloride into the tissues to dilute the neosarsphenamine solution but also because I have found that the procaine not only relieves immediately but because the resulting tissue reaction is much less than with the use of all other solutions that have been recommended. I have thus used procaine hydrochloride for more than twenty-five years, and, though during my years of teaching I always told my classes about it, it may be that giving this information wider publicity may save other physicians and patients considerable annoyance. I am making no claim to priority. Others before me may have used this method or may even have published a description of it.

RÉNÉ BINE, M.D., San Francisco.

PERNICIOUS VOMITING OF PREGNANCY

To the Editor:—On page 223 of THE JOURNAL, May 20, in a communication from a London correspondent, there is a discussion on the subject of hyperemesis gravidarum, pointing out two causative factors, hepatic necrosis versus hysteria.

In a small series each patient was given 100 mg. of thiamine hydrochloride intramuscularly every other day, with dramatic and startling results. The pernicious vomiting in all instances cleared after the fourth or fifth injection. Fifty per cent improvement had been noticed after the first injection. Every patient made a remarkable gain in weight within a week's time and went on a general diet without recurrence at any time during the current pregnancy. One patient's remark was interesting and characteristic: "I have been vomiting during my three pregnancies, even several days after I have been delivered. Every child was delivered in a different city by a different doctor, since we belong to the theatrical profession. This fourth pregnancy was the worse, but the 'shots stopped it.' I wish the other doctors would have done the same thing."

The theory of Sir Arthur Hurst of hepatic necrosis is substantiated by the facts that prior to the advent of thiamine a similar series of patients had been treated with glycogen enemata and later with a carbohydrate diet, with satisfactory results in the majority of cases but rather slowly, one to two months elapsing before improvement was noticed. With the thiamine therapy the results are accomplished in three to five days in the most pernicious cases of hyperemesis gravidarum.

Sir Arthur Hurst's theory with reference to hepatic necrosis is substantiated by the observation that an increase of glycogen to the liver cells either by glycogen or by glucose enemata from 25 per cent to 50 per cent in strength four times a day or as thiamine, which aids in the metabolism of carbohydrates and a greater deposition of glycogen into the liver cells, may bring about a condition which checks it completely and entirely with a simple and harmless agent.

In one of my last visits to the late Dr. Joseph B. De Lee, this new treatment for hyperemesis was related to him and he was very much interested. He suggested that it be tried at the Maxwell Street Maternity Center.

MEYER M. MARBEL, M.D., Chicago.

POTENTIAL DANGER OF SELF MEDICATION WITH FLUORIDES

To the Editor:—The subject of fluorine and its relation to dental caries is one which is receiving wide publicity in both the professional and the lay press. It has come to my attention that some dentists are advising their patients to use mouth washes containing sodium fluoride for self medication, and some of the solutions prescribed are as potent as 1 and 2 per cent

solutions. Sodium fluoride is a highly toxic substance, and while its application in safe concentrations, under strict control by competent personnel, may prove to be a useful therapeutic agent, under other circumstances it may be definitely harmful.

DAVID B. AST, D.D.S., Albany, N. Y.
Assistant Director for Oral Hygiene, Division
of Maternity, Infancy and Child Hygiene.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

EXAMINING BOARDS IN SPECIALTIES

Examinations of the Examining Boards in Specialties were published in THE JOURNAL, July 15, page 810.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, Oct. 24-26. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, September 5. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

CONNECTICUT: * Endorsement. New Haven, July 25. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: Dover, Oct. 10-12. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * Washington, November. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

INDIANA: Indianapolis, Jan. 3-5. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 301 State House, Indianapolis 4.

IOWA: * Iowa City, Sept. 25-27. Dir. Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Nov. 2-3. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

KENTUCKY: Louisville, Sept. 11-12. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville.

LOUISIANA: September. * Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MICHIGAN: * Ann Arbor, July 24-26. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

MINNESOTA: * Minneapolis, Aug. 29-31. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSOURI: St. Louis, Sept. 18-20. Sec., State Board of Health, Dr. James Stewart, State Capitol Bldg., Jefferson City.

MONTANA: Helena, Oct. 2-4. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEBRASKA: * Omaha, Sept. 26-28. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

NEVADA: Carson City, Aug. 7. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.

NEW MEXICO: * Santa Fe, Oct. 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH CAROLINA: Raleigh, Sept. 11-12. Sec., Dr. W. D. James, Hamlet.

OHIO: Examination. Columbus, Sept. 26-29. Endorsement. Columbus, Oct. 3. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, Sept. 16. Sec., Dr. J. D. Osborn, Jr., Frederick.

OREGON: * Portland, July 26-27. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

SOUTH CAROLINA: Charleston, Sept. 11-13. Sec., Dr. N. B. Heyward, 1329 Blandena St., Columbia.

VERMONT: Burlington, Sept. 12-14. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA: Richmond, Sept. 19-22. Sec., Dr. J. W. Preston, 30 1/2 Franklin Rd., Roanoke.

WEST VIRGINIA: Charleston, Oct. 2-4. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

DISTRICT OF COLUMBIA: Washington, October. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, Nov. 4. Final date for filing application is Oct. 20. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

MICHIGAN: Ann Arbor and Detroit, Oct. 13-14. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

RHODE ISLAND: Providence, Aug. 16. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Explosion of Bulb in Diathermy Lamp.—The patient suffered from arthritis and neuritis and at intervals for about four years submitted to diathermy treatments administered by the physician defendant in his office. Dec 6, 1940 she lay on a table with her back exposed to an infra-red deep therapy lamp about 2½ feet distant, having a 1,000 watt bulb. After she had been in this position for about fifteen minutes the light bulb exploded without warning and hot glass fell on her body, causing severe burns. She and her husband instituted an action for malpractice against the physician. In an attempt to produce evidence tending to prove negligence on the part of the physician, she called him as her witness and the physician testified that he had made no inspection of the light globe that exploded and could make none, other than turning it on to see if it was working, that he did not know what caused the globe to explode, that he had never heard of one exploding before, that there was no noticeable defect in the globe, that he had had globes of this type burning continuously for as much as seven hours without trouble, that there are hundreds of lamps of this type in use, that he frequently used this same lamp ten or twelve times a day, that the bulb in question was a standard one in general use, and that no manufacturer, so far as he knew, had ever theretofore recommended the screening of such lamps as a precautionary measure. At the close of the plaintiff's testimony the court entered a judgment for the physician, and the plaintiff appealed to the district court of appeals, fourth district, California.

The sole question to be decided here, said the appellate court, is whether or not the fact that the lamp globe exploded so speaks for itself as to justify an inference that the explosion occurred because of some negligent act on the part of the physician. In other words, under the facts of the present case can the doctrine of *res ipsa loquitur* be applied? The plaintiffs argued that this is one of that class of malpractice cases in which the acts done are so patently negligent that no expert testimony is required and from the occurrence of the incident alone negligence on the part of the physician may be inferred, citing *Ales v Ryan*, 8 Cal (2d) 82, 64 P (2d) 409, *Ragin v Zimmerman*, 206 Cal 723, 276 P 107, *Moore v Steen*, 102 Cal App 723, 283 P 833, *Brown v Shortridge*, 98 Cal App 352, 277 P 134, and *Bence v Denbo*, 98 Ind App 52, 183 N E 326. In the cases cited by the patient, said the court, respectively, a sponge was left in a patient during an operation, burns were suffered from too long or improper exposure to an x-ray machine, a surgeon while removing tonsils had knocked out one of the patient's teeth, and an x-ray machine had been so handled that it was permitted to fall on the face of the patient. In those cases no proof of a special standard of care was required and the doctrine of *res ipsa loquitur* was held applicable. The plaintiffs argued that the doctrine applicable in those cases is applicable also in cases in which injury has been caused by mechanical equipment which is under the exclusive control of the defendant. In support of that argument they first cited *Chaurin v Arpin*, 4 Cal App (2d) 322, 40 P (2d) 904, in which the plaintiff was burned while being given a permanent wave in a beauty shop. The court in that case said

The injury was one which in the natural course of things would not have occurred had defendants used due care, and plaintiff was therefore entitled to recover, unless the defendants offered a satisfactory explanation to overcome the presumptive evidence of their negligence.

The plaintiffs next cited *Helms v Pacific Gas & Elec Co*, 21 Cal App (2d) 711, 70 P (2d) 247, where the plaintiff had been injured while standing on a sidewalk by a falling portion of the glass globe of an electrolier. It was held in that case, in effect, that the danger could have been known by the defendant and that the question of whether proper inspection had

been made was one for the jury. The plaintiffs next cited *Wundas v Galston & Sutton Theatres*, 35 Cal App (2d) 533, 96 P (2d) 170, in which the injury involved was the result of a block of plaster falling from the ceiling. In holding the doctrine of *res ipsa loquitur* applicable in that case, the court there observed that plaster does not ordinarily fall from a ceiling if proper care is used to see that the ceiling is safe. In the cases cited by the plaintiffs, said the appellate court, it is pointed out that the *res ipsa loquitur* doctrine is applicable where it appears that the accident is of a kind which ordinarily does not occur in the absence of negligence on the part of the one having the management or control of the thing which caused the injury. The doctrine is further based on the theory that the defendant, having charge of the instrumentality in question, either knows the cause of the accident or had a means of knowledge in that connection which was superior to that possessed by the injured party. But, as was said in *Johnson v Ostrom*, 128 Cal App 38, 16 P (2d) 794

The converse of this rule is likewise true. If the evidence affirmatively shows that operator or manager of the instrumentality by means of which the injuries are inflicted has no superior knowledge or by the exercise of reasonable care is unable to secure information regarding the cause of the accident, or the evidence establishes the fact that the complainant possesses all the knowledge or information thereof which is reasonably accessible to the operator of the machine, then the doctrine of *res ipsa loquitur* has no application.

In this case, continued the court, there was no evidence tending to show why this light globe exploded or tending to show that the accident was one which, according to common experience, would not ordinarily occur except through some fault of the physician. In other words, there was no evidence justifying any inference that any amount of care which might have been exercised by the physician would have prevented the explosion or that he failed to use proper care. There is nothing in the evidence or in common experience which would justify an inference that an inspection could have been made which could have been of any avail in disclosing any defect which might have been expected to cause such an explosion. As is well known, such a light globe is a sealed unit which cannot be inspected in any manner which might be material here.

The physician, continued the court, possessed no knowledge as far as anything which caused this accident is concerned which was superior to that possessed by his patient. There is nothing in common experience which would suggest that the explosion which here occurred was one which would not have taken place except for the negligence of the physician, and it may not even be said that the physician had the management or control of the instrumentality in the sense that he had it within his power to control anything which caused the explosion. The complaint filed by the plaintiffs alleged that the physician so carelessly and unskillfully used, operated and controlled the electric lamp that he caused the injuries to his patient. There is no evidence to support that allegation and under the circumstances which here appear no inference is possible that the explosion occurred only because of negligence on the part of the physician and the doctrine of *res ipsa loquitur* is consequently not applicable.

The judgment in favor of the physician was accordingly affirmed.—*Crouce v McBride*, 149 P (2d) 69 (Calif, 1941)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pain in Chest, Particularly in Angina Pectoris.—Harrison states that pain in the chest is present in from 15 to 25 per cent of all adult patients who need hospitalization. A study has been carried on for a number of years and has dealt with several hundred patients. The present report presents an analysis of 77 patients with angina pectoris. The author applies the term angina pectoris to a condition characterized by recurrent attacks of discomfort in or near the chest, commonly induced by conditions which impose an additional burden on the heart, ordinarily dependent on disturbance of the oxidative processes in the myocardium and always attended by the likelihood of sudden death. The pain was felt in the substernal location in only about half of the patients. Pain entirely limited to the periaxillary, axillary or abdominal regions did not occur. The pain usually lasted only a few minutes, rarely longer than thirty minutes. No patient had pain lasting for only a few seconds. Pain of great intensity was exceptional, the discomfort being mild or minimal in more than half of the cases. The discomfort was constrictive or heavy in character in only about 50 per cent of the cases. Frequently the pain was of an aching quality. In addition to the generally recognized "trigger" factors of exertion, eating, emotion and cold, the recumbent posture and glucose deficiency were found to be common precipitating causes of the seizures. In exceptional cases anginal attacks with typical electrocardiographic changes may be induced by spontaneous hypoglycemia in patients who have no seizures with severe effort and no evidence of structural heart disease. The act of eating may precipitate anginal attacks in certain cases and may prevent them in others. Pain induced by the sitting or standing position or aggravated by breathing, coughing or swallowing can usually be ascribed to disorders other than angina pectoris. The most important features in the diagnosis of angina pectoris are (1) the history of relationship to effort, (2) the short duration of the pain and (3) the demonstration that the amount of muscular effort required to induce the pain is increased by glyceryl trinitrate. A large percentage of patients with angina pectoris also suffer from chest pain due to other disorders. Such disorders may either be related to angina pectoris (as in the case of myocardial infarction and

reflex disturbances of the skeletal system) or unrelated to it (as in the case of gallbladder disease, hiatal hernia, esophageal spasm and the like). Because of the frequent coexistence of two causes of chest pain, one of them may be overlooked unless unusual care is employed in obtaining the history.

Treatment of "Irreversible" Shock.—Levine and his associates induced an irreversible stage of shock in 64 dogs. All the animals died when no treatment was given, and only 25 per cent survived when whole blood was used to replace the total amount bled. When the desired criteria for "irreversible" shock were obtained, different groups of animals were treated in different ways. Except for the first control group all animals were reinfused with the total amount of blood which had been withdrawn minus the amount lost by sampling and by unavoidable waste. In the second control group the difference between the amount of blood withdrawn and that available for reinfusion was replaced by isotonic solution of sodium chloride. The third group was given whole blood and sodium succinate, the fourth group whole blood and sodium lactate, the fifth group whole blood and sodium bicarbonate, the sixth group whole blood and dextrose, the seventh group whole blood and dextrose and sodium bicarbonate. Throughout these experiments the animals either died within eighteen hours after the institution of therapy or survived indefinitely. The authors think that their results hold promise of improved mortality statistics for the treatment of far advanced shock on the battlefield. Because whole blood is not readily available under those conditions, blood plasma supplemented with sodium bicarbonate and dextrose must be tested. It is suggested that a sweetened alkaline drink might be of prophylactic value for injured men in early shock, for whom prompt blood volume replacement is not likely to be available. The authors stress that acidosis, while not a cause of shock, is an important factor in determining the reversibility of far advanced shock. Whole blood supplemented by sodium bicarbonate and dextrose resulted in the survival of 62.5 per cent of dogs brought to the stage of so-called irreversible shock.

Effect of Aluminum Hydroxide Gel on Gastric Secretion.—Adams and Clark investigated the effects of aluminum hydroxide gel in moderate dosage when it was administered three times daily after a test meal for five consecutive days. The authors used Cope pouch dogs to determine the effect of moderate doses of sodium hydroxide gel on pouch secretion. They found that no depression of secretory activity occurred either during or after the administration of the antacid. The administration of moderate doses of aluminum hydroxide gel

was accompanied by occasional increases in volume, total chloride, total base and free acid of the pouch secretion, but in the majority of experiments these increases were too small to be significant.

Roentgen Irradiation in Cancer of Larynx.—Blady and Chamberlain present a five year survival study on 36 cases of cancer of the larynx treated with radiation. The treatment with radiation was selected for one or several of the following reasons: (1) presence of metastases in the neck on admission; (2) disease process too extensive for surgery; (3) suggested radiosensitivity of the tumor as determined by biopsy; (4) advanced age and poor operative risk; (5) complicating cardiac and renal disease; (6) recurrence after laryngofissure; (7) operation refused by the patient. Twenty-three patients had cancer of the intrinsic and 13 of the extrinsic larynx. The term "cancer of the intrinsic larynx" denotes origin of the tumor on the vocal cords, the ventricles or the subglottic region, while "cancer of the extrinsic larynx" includes origin on the arytenoids, aryepiglottic folds, base of the epiglottis and upper surface of the piriform sinuses. Intrinsic cancer is predominantly of squamous cell, grade 2, variety, whereas the extrinsic is usually of grade 3 or 4. Squamous cell carcinoma grade 2 is a radiosensitive growth when limited to the intrinsic larynx. Of the four recurrences in the intrinsic group, three were grade 3 and one was grade 2. Metastases are infrequently observed in intrinsic laryngeal cancer. Of patients who did not develop metastases at any time, 71 per cent survived more than five years. Of the extrinsic group 46 per cent had metastases on admission and none of these patients survived. For the intrinsic group treated with roentgen radiation, the net five year survival without evidence of recurrent or metastatic disease is 59 per cent while for the extrinsic group it is 25 per cent.

Amphetamine and Dextrodesoxyephedrine in Irradiation Sickness.—Jenkinson and Brown investigated irradiation sickness because of the prevalence of physical incapacity among patients receiving intensive roentgen therapy. An inhibiting effect on the gastrointestinal tract indicated possible benefit to the nausea and vomiting. Dextrodesoxyephedrine was studied because of its similarities to amphetamine. The authors review the therapeutic effect of amphetamine or dextrodesoxyephedrine on 69 patients with symptoms of irradiation sickness. A proposed hypothesis concerning the basic mechanism of irradiation sickness indicates the role of local and general increased capillary permeability. The pharmacology of amphetamine and d-desoxyephedrine indicates that they are of therapeutic value in irradiation sickness by their action in maintaining the peripheral circulating blood volume and preventing visceral stasis and splanchnic dilatation. The effectiveness is reduced by anemia, by nutritional and metabolic changes associated with debilitation, and by extensive metastases. The present study indicates that the management of irradiation sickness should include (a) A critical evaluation of each patient's physical condition prior to roentgen therapy. Corrective measures should be instituted in the presence of anemia, dehydration, acidosis, the deficiencies associated with debilitation and nutritional disturbances. (b) A prophylactic use of small oral doses of amphetamine or d-desoxyephedrine, increasing the dose with the first evidence of increasing weakness or lassitude. (c) A prophylactic use of the water soluble vitamins, which are readily depleted by disturbance of the digestive and absorptive mechanism. Evaluation of the therapeutic effect of amphetamine and d-desoxyephedrine indicates that the greatest value is in combating the weakness, exhaustion and lassitude of irradiation sickness.

Night Vision.—Kekcheev points out that methods developed in prewar days for changing visual thresholds by application of caffeine or strychnine had been only of laboratory interest. The literature offered a few suggestions for altering the threshold of certain sensory organs by stimulating other sensory organs. It was established that the stimulation of any external sensory organ (hearing, smell, touch and taste) may augment or diminish the thresholds of visual perception. The author showed that a change in the acuity of night vision produced by stimulation of other sensory organs was not an isolated process but was part of a diffuse autonomic reflex. The thresholds of night vision varied with the pulse rate, the blood pressure level, respiration and electrical resistance of the skin to direct current. Not all stimuli were equally effective in raising the threshold of night vision. Taste, cold and proprioceptive (moderate effort) stimuli were chosen as being the most practical and convenient. During drowsiness the sensitivity of the eye shows a sharp decrease. The application of cold not only restores vision and hearing but terminates drowsiness as well. By applying taste, cold and proprioceptive stimuli the dark adaptation period was reduced to from five to six minutes. The acceleration of the dark adaptation period is of a great practical importance under battle conditions, for instance for night fliers, who must discern the enemy bomber in the gloom of the night in so-called dazz-

ling of the eyes by a searchlight, rocket or the flash of tracer bullets. Experiments carried out in 1943 in the writer's laboratory in Moscow showed that the use of red eyeglasses five to ten minutes after the white light has begun to act promptly restored vision to its normal threshold and occasionally intensified it. Thus the same white light which had previously destroyed the sensitivity of the dark adapted eye increased that sensitivity when filtered through red glasses.

Nature and Origin of Altitude Pains.—Ascents to a rarefied atmosphere and prolonged stay at low barometric pressure may produce pains which are most frequently localized in joints and surrounding tissues. In some cases the pain in the joint is accompanied by acute subjective disorders, such as dizziness, pallor, excessive perspiration, nausea and a feeling of faintness. Malaise, weakness, dyspnea, chills and high temperature continue for several hours on return to normal pressure. The pain disappears, but a feeling of awkwardness and heaviness in the involved extremity persists for from one to two hours. Some investigators regard altitude sickness as the result of hypoxemia, others believe that altitude pains are a manifestation of a rheumatoid syndrome. Still another hypothesis is that altitude pains are symptoms of caisson disease in which, on decompression, nitrogen bubbles are released in the tissues. The author reports observations on aviators and experiments on goats, dogs and rabbits. He assumed that the caisson theory was correct and that the pains resulted when nitrogen was released from the fluids and tissues through decompression. The experiments were based on the further assumption that altitude pains would not occur if the nitrogen was "washed out" of the organism prior to the ascent. Ten men did not have altitude pain after nitrogen elimination, although they did have pain in almost all control ascents at lower altitudes. Most of the animals in the author's experiments developed the classic picture of caisson disease. Postmortem studies on the animals which died as a result of rapid decompression revealed typical symptoms of acute caisson disease. Numerous gas emboli were found in the vascular system and in the synovial fluid of the joints in all cases. The adipose tissue, especially in the abdominal cavity, was friable on palpation.

Postoperative Salt Intolerance.—Collier and his associates show that although the body of a normal person is generally capable of handling relatively large amounts of isotonic saline solutions without showing significant derangement in the regulation of body functions there are many patients who are incapable of tolerating relatively small excesses of salt solution during the immediate postoperative period. The type of illness that may follow the administration of saline or isotonic solution of three chlorides varies. There are three predominant and fairly distinctive symptoms and sign complexes. Because of the relatively high incidence of salt intolerance following a general

anesthetic, no isotonic saline solution or isotonic solution of three chlorides should be given during the day of operation and during the subsequent first two postoperative days. The fluid requirement of the patient is met with dextrose solution. If a significant loss of extracellular fluid occurs during the foregoing period, it is replaced with 0.5 per cent sodium chloride solution to which 50 Gm. per liter of dextrose has been added. Isotonic saline solution (0.9 per cent) or isotonic solution of three chlorides is used to replace extracellular fluid loss after the postoperative urinary suppression has disappeared, usually after the second postoperative day. Great care must be used in administering isotonic saline solution and isotonic solution of three chlorides to patients who are hypoproteinemic, anemic, acidotic or oliguric. The authors recommend that the correction of uncompensated extracellular fluid deficiency states be made on the basis of the physiologic response to test doses of the appropriate salt solution rather than on the basis of the plasma chloride, the carbon dioxide combining power, the non-protein nitrogen, the plasma protein or the hemoglobin levels.

Chronic Cystic Mastitis.—Cole and Rossiter make a plea for a classification which would be of clinical as well as of pathologic significance. Their classification is based on two factors: the predominance of the pathologic lesion present and the relative danger of transformation to carcinoma. The following groups are included: (1) adenofibrosis, (2) benign parenchymatous hyperplasia, (3) precancerous hyperplasia and (4) cystic disease. A single specimen may exhibit gradations of all four types described, but with few exceptions one of them predominates. This classification is based on the supposition that carcinoma may at times be superimposed on chronic cystic mastitis. Carcinoma can and does develop in certain types of chronic cystic mastitis. It is most apt to develop in precancerous hyperplasia, which is in itself a benign disease. This lesion consists of an epithelial hyperplasia which resembles that seen in carcinoma. The hyperplasia exceeds the benign limits characterizing parenchymatous hyperplasia yet lacks the invasiveness and anaplasia of cancer. This is a controversial group, clinically speaking, as it is impossible to tell which of these cases will go on to actual malignancy. The authors have seen this lesion in close proximity to unquestioned cancer and have seen cancer develop in breasts known to harbor such changes through biopsy at some previous time. In view of the possibility of the development of carcinoma in precancerous hyperplasia, the authors recommend simple mastectomy if removal of a nodule reveals a hyperplasia of the precancerous type. Adenofibrosis and cystic disease are least susceptible to malignant change and, fortunately, are readily distinguishable clinically and pathologically from parenchymatous hyperplasia and precancerous hyperplasia.

Fatalities in Electric Shock Treatment of Psychoses.—Gralnick reports two deaths associated with electric shock treatment. The first patient died one week after her fourteenth treatment in a hyperpyretic state associated with status epilepticus; the second two days after his second treatment. No definite conclusion can be made with respect to the first case because of the absence of autopsy evidence. The acute nature of her death suggests some connection between the two events. It is possible that in this patient, as in a few of the cats studied by Alpers and Hughes, hemorrhages occurred in the hypothalamic region which were sufficient to cause the hyperpyrexia and status epilepticus. The fact that the patient died one week after her last treatment speaks against this possibility, but the

exact time of occurrence of hemorrhage is not known. It is also possible that the current produced damage to the cells in the region of the already labile heat regulating center. These changes could have been associated with punctate hemorrhages and subsequent edema to produce the same result. Necropsy studies on the second patient disclosed evidence of cerebrovascular syphilis and other changes which were possibly due to the treatment itself. The alterations were not sufficient to account for death. The cause of death after electric shock treatment is still obscure. Electric treatment has attendant serious dangers and should not be given to patients with a history of vascular or cerebral disease.

Fever and Sulfadiazine Therapy in Resistant Gonorrhea.—Licht and Dick treated 119 young men with recently acquired, sulfonamide resistant, gonorrhea by combined drug and fever therapy. All had failed to respond to two or more courses of sulfonamide compounds, each course consisting of at least 20 Gm. of drug given in five days. On the day preceding fever treatment fluids were forced up to 3,000 cc. and carbohydrates were given in the form of sweetened orange juice. During the fever treatment fluids were given by mouth in the form of 0.3 per cent iced salt solution. An intake of more than 400 cc. per hour was discouraged because of the regurgitation seen after forced drinking. Oxygen was given continuously through a nasal catheter. Originally the authors administered 10 Gm. of sulfadiazine in divided doses during the eighteen hours immediately preceding treatment. This produced excessively high blood concentration in some patients. A trial administration was made to determine the amount of medication required to attain a blood concentration of from 11 to 12 mg. per hundred cubic centimeters when fever would be started. When the drug is administered up to the hour of treatment it remains in the stomach and may provoke vomiting. By changing the schedule of drug ingestion so that the last dose was given at or before 5 a. m. instead of at 7 a. m., the incidence of vomiting during treatment was reduced. The duration of the fever should depend on the tolerance of the patient. Eight hours is most desirable, but there should be no hesitancy in discontinuing it and repeating the treatment if necessary.

Aluminum Powder in Treatment of Silicosis.—A clinic was established at Timmins, Ont., where a large number of silicotic subjects could be observed. Only men who were still exposed to silica dust and who had uncomplicated silicosis with

measurable pulmonary disability were chosen for treatment with aluminum powder. Before treatment was instituted, each worker was carefully studied and respiratory function tests were carried out. The latter included a study of total lung volume and pulmonary ratios as described by McCann and his co-workers. Pulmonary ventilation studies were also made. Selected men were treated with daily inhalation of fine aluminum powder, freshly ground from small aluminum pellets in a specially constructed mill. Treatment was given just before or after a shift. Treatment was begun by five minutes' inhalation through the powder mill. This period was gradually increased to thirty minutes daily and was continued in some cases almost a year, a small number of men receiving approximately 300 treatments, the majority receiving about 200. About 50 patients have received this form of therapy; 34 of whom have completed the course prescribed. It was shown conclusively that the administration of aluminum powder is entirely harmless. Out of 34 cases studied 19 have shown clinical improvement, apparent chiefly in the lessening or disappearance of shortness of breath, cough, pain in the chest and fatigue. A reduction in the incidence of colds and a gain in weight have also been observed in many patients. While the condition of 15 patients has remained stationary, it must be emphasized that they are no worse and their condition has not progressed in spite of continuous employment in silica dust during the period of investigation. Respiratory function tests, repeated at intervals of about every three months, have shown improvement in 12, or about one third, of the treated cases. While 22 remained stationary, they are no worse in spite of continued exposure to silica dust. Six of a group of 9 controls, untreated by aluminum, have shown progression of their disease while under observation. Aluminum dust cannot be regarded in any sense as a "cure" for silicosis as far as restoring to normal lung tissue which has already undergone fibrotic change is concerned. Its use is followed by beneficial results in a significant proportion of cases, chiefly in the amelioration of symptoms and in the increased capacity to work.

Patent Urachus.—Patent urachus is rare, only 148 cases having been reported in the last four hundred years. Atcheson reports 2 army privates with this abnormality observed within one month at his station hospital. The generally accepted theory is that the urachus is the result of the bladder developing in the region of the umbilicus and later withdrawing deep into the pelvis. The result is a cone shaped outgrowth from the dome of the bladder with its apex at the umbilicus. Eventually the entire tube becomes smaller until it finally closes off from the bladder. When it does not close, it is known as a patent urachus. There are four possible anomalies which may result from this process going astray: 1. The tube may open into the bladder but not reach the umbilicus. 2. It may open at the umbilicus and not reach the bladder. 3. It may extend from the bladder to the umbilicus as a fistula. 4. It may close off in sections and form small cysts. Patent urachus may easily be confused with intra-abdominal conditions, such as acute appendicitis and cystic tumors, if a history of drainage from the umbilicus is not obtained. In some cases the urachus will change from one type to another. In the 2 cases presented both existed as fistulous types, as evidenced by the history of

urine draining in early life. As the inflammatory changes occurred, the fistula sealed off and the sinus type resulted. It is suggested that the peritoneum be routinely opened at a point below the umbilicus and the attached tract and umbilicus be excised in toto. An important part of the therapy is the treatment of the infection in the tract before the surgical intervention. This can be done by drainage and irrigation with a solution such as azochloramide.

Crude Liver Extract as Aid to Metal Therapy.—Astrachan presents data on the value of crude liver extract in patients with intolerance to arsenicals or heavy metals. He reports observations on 114 patients. Crude liver extract is a useful supportive measure. It prevents some manifestations due to intolerance to arsenicals or heavy metal, especially in cases of gastrointestinal disturbances (improvement in 60 per cent of the cases). A few patients with pruritus and mild skin manifestations were also benefited by liver therapy. Best results were obtained in cases in which the largest number of liver extract injections were administered. These injections cause a decrease of the icterus indexes and thus improve the impaired function of the liver. Caution must be observed in administering liver extract. In some cases the intravenous method of administration may be used.

Histopathology of Radiation Lesions.—Warren discusses lesions caused by types of radiations used therapeutically, such as electromagnetic radiation of a wavelength ranging from 10 to 0.05 angstroms, corpuscular radiation as the alpha and beta radiation from radium or certain of the temporarily radioactive isotopes, and neutrons. Tissues or tumors are classified as radiosensitive if there is gross change with radiation of less than 2,500 roentgens given under ordinary therapeutic conditions. Such radiation does not usually injure most tissues permanently. A tissue is considered radioresponsive if such alteration occurs with a range between 2,500 and 5,000 roentgens and radioresistant if over 5,000 roentgens is required for a response. At or above this dose some permanent injury is done to a number of normal tissues. It is important not to confuse radiosensitivity of a tumor with radiocurability of that tumor. Thus a lymphosarcoma is highly radiosensitive but rarely cured, while epidermoid carcinoma grade 1 of the lip is resistant but often cured if the dose is sufficient. Many of the tumors that respond well to radiation initially will recur, usually in a form more resistant to radiation than were the cells of the original tumor. While in general the radiosensitivity of tumors tends to follow that of the type cell from which they are derived, striking variations exist. There are also variations in sensitivity determined by the stroma of the tumors.

A relatively acellular supporting tissue, such as cartilage or bone, gives a less favorable therapeutic reaction than does a cellular one, as newly formed connective tissue or invaded muscle. For example, a basal cell carcinoma of the skin is easily cured by radiation when located on the cheek, whereas one occurring on the forehead invading the frontal bone is extremely resistant. Increased amounts of intercellular substance in the supporting tissue of the tumor or secondary infection tend to increase resistance, whereas a greater degree of vascularity tends to decrease resistance.

Therapeutic Efficacy of Penicillin in Relapsing Fever Infections in Mice and Rats. H. Eagle, H. J. Magnuson and Arlyne D. Musselman.—p. 583.

Penicillin in Relapsing Fever in Mice and Rats.—Eagle and Magnuson studied the efficacy of penicillin in white rats and mice experimentally infected with *Borrelia novyi*, which causes relapsing fever in North America. The total dosages of penicillin which "cured" 50 per cent of white rats and mice infected with *Borrelia novyi* were 130,000 units and 100,000 units per kilogram respectively. Approximately 400,000 units per kilogram was necessary to cure more than 95 per cent of the animals. This was half the dose which killed a significant proportion of the rats. If these results can be translated to man, they imply that the curative dose of penicillin in man would be on the order of 25,000,000 units. Unless relapsing fever is more amenable to treatment in man than it is in these experimental animals, or unless other strains of the organism prove more susceptible to penicillin, the therapeutic use of the drug would not appear warranted except in arsenic resistant cases, at least until such time as it is available in larger quantities.

Hypertension in Prognosis of Bleeding Ulcer.—Rafsky and Weingarten stress that in evaluating cases of bleeding ulcer it is necessary that the severity of bleeding and complicating diseases be considered. They report observations on 476 patients.

with bleeding peptic ulcer of whom 80, or 16.8 per cent, had systolic blood pressures of hypertensive level. This is in contrast to an estimated incidence of 40 per cent of hypertensive or prehypertensive levels in the general population. Probably many more of these 476 patients were hypertensive, but no hypertension was observed during and shortly after their bleeding episodes. The authors compare the mortality and the severity of bleeding of patients with and without hypertension; also the comparative mortality below and above 50 years of age. Hypertension in a patient with bleeding peptic ulcer has little effect on the severity of the bleeding. The gross mortality in patients under 50 years of age with hypertension was increased, but this high mortality was due largely to the presence of complicating diseases not found in patients without hypertension. In patients over 50 years of age the mortality was approximately the same for those with and without hypertension, because arteriosclerosis leads to the same complications as hypertension. Indirect citrated transfusions of blood and intravenous infusions of saline solution and dextrose should be used freely to combat anemia and shock in bleeding peptic ulcer without fear of their effect on blood pressure.

Wound Disruption.—Tashiro applies the term disruption to cases in which any portion of the peritoneal cavity or its contents presented in the wound. Synonyms for this condition are dehiscence, rupture, eventration, evisceration, avulsion and separation. A review of the operating room files of the Cincinnati General Hospital for the ten years that began with January 1933 shows that there were 55 eviscerations of laparotomy wounds during that period. There were 40 males and 15 females. Some observers believe that males are more subject to wound disruption than females. Sixty per cent of the cases observed by the author occurred during winter and spring. In northern Europe likewise there is a higher incidence of eviscerations during these seasons. Hartzell and his associates stress the role of protein and vitamin C deficiency. The work of Ingalls and his colleagues directs attention to hypoproteinemia. Some dispute the influence of subnormal plasma protein, others ascribe a major role to vitamin C deficiency and still others believe that strains and intra-abdominal pressure play a part. Lahey thinks that seratomas and hematomas are the cause of disruption. Freeman suggested incomplete closure of the peritoneum as the causal factor and others suggest allergy to catgut, decreased pH and infection. The author comes to the conclusion that wound disruption results from a combination of factors including postoperative strains, primary or associated debilitating disease, hypoproteinemia and vitamin C deficiency. He also gained the impression that those patients who survive secondary closure are apparently predisposed to intestinal obstruction and hernia.

Saline Solution, Washed Red Cells or Heparinized Plasma in Shock.—McKee and his associates report the effect of saline solution plasma and washed red cells on dogs which were in a state of posthemorrhagic circulatory collapse, commonly referred to as shock. Whole blood or plasma has been accepted as the treatment of choice in shock. Washed red cells have been considered a rather poor blood substitute in spite of the fact that the majority of the effects of hemorrhagic shock can be explained on the basis of anoxia. The authors think that the efficacy of a blood substitute depends on its ability to maintain a satisfactory circulatory state. They produced hemorrhagic shock in dogs in the following manner: Under local anesthesia, the femoral artery and vein are cannulated. The animal is bled from the artery until the blood flow has practically ceased and is then perfused with 23 cc. per kilogram of 0.9 per cent sodium chloride solution through the vein to wash out more red cells and plasma. When the bleeding has again practically ceased, the artery is ligated and the volume of test solution equivalent to the first bleeding given immediately into the vein. Following this the vein is ligated and the wound is closed. In these experiments washed red cells suspended in isotonic solution of sodium chloride are found to be more effective than either isotonic solution alone or heparinized plasma in overcoming shock produced by a single severe hemorrhage. Replacement of the oxygen carrying capacity of the blood appears to be more important than the restoration of the normal plasma protein level under the conditions of these experiments. As an emergency measure isotonic solution of sodium chloride is shown to be effective in promoting temporary recovery from hemorrhagic shock as produced by a single massive hemorrhage.

Administration of Alkalis in Sulfadiazine Therapy.—According to Rohr and Christopher renal complications of sulfadiazine therapy can be prevented by the production and maintenance of an alkaline urine, and alkalinity of the urine can be maintained either by giving from 4 to 19.5 Gm. of sodium bicarbonate daily or, as suggested by Bywaters in 1942, by the use of one-sixth molar sodium r-lactate intravenously. Since immediately after operation patients cannot be given oral medication, the author aimed to determine a practicable method for rapidly producing alkaline urine for the safe intravenous administration of sodium sulfadiazine and for keeping the urine alkaline up to the time the sodium bicarbonate could be given orally. In 20 cases following operation the pH of 422 specimens of urine was determined, beginning twenty-four hours prior to and continuing for five days after starting alkaline therapy. Each specimen was tested with nitrazine paper within a few minutes after being voided. Specimens were examined microscopically at least once daily for sulfadiazine crystals, red blood cells and casts. The authors found that one-sixth molar sodium r-lactate intravenously was efficient for the rapid production of urinary alkalinity in that 1,000 cc. maintained urinary alkalinity for an average of twenty-four hours. At least 24 Gm. daily of sodium bicarbonate was necessary to maintain urinary alkalinity after the intravenous administration of fluids was discontinued. Renal complications were not found after sulfadiazine administration when the urine was rendered alkaline. Sodium sulfadiazine should not be mixed with or come in contact with one-sixth molar sodium r-lactate in the intravenous set.

Toxicopathic and Trophopathic Hepatitis.—Himsworth and Glynn compare necrosis of the liver in experimental animals with similar conditions in man. Experimental necrosis of the liver can be produced by certain poisons of chemical or vital origin or by lack of a nutritive factor contained in protein. The term "toxic necrosis" is generally used to describe all types of necrosis associated with exposure to poisons; it is not limited to those produced by the direct action of a poison on the liver cells. A term is required with the latter restricted meaning, and the authors propose the term "toxicopathic." A term is also required to distinguish necrosis due to deficiency of a nutritive factor. For this the authors suggest the term "trophopathic." Experimental toxicopathic hepatitis develops in rats rapidly after exposure to poison. The liver shows a diffuse zonal necrosis. In survivors recovery is complete. Repeated exposures to poison, however, produce a diffuse hepatic fibrosis. Experimental trophopathic hepatitis develops only after a long latent period. The liver shows massive necrosis which always leads to postnecrotic scarring and, in severe cases, to nodular hyperplasia. In man the hepatitis following exposure to such poisons as chloroform, phosphorus and carbon tetrachloride has the features characteristic of toxicopathic hepatitis. The zonal hepatitis seen in eclampsia and infective hepatitis and after treatment with the organic arsenical preparations also appears to be of this type. In man massive hepatic necrosis, and its sequel nodular hyperplasia, may be attributed to a trophopathic hepatitis. There is suggestive evidence that this can arise as the result of a dietary deficiency, but most commonly it develops as a complication of a preceding illness, and it is then to be regarded as a conditioned deficiency disease distinct and separate from the illness which it complicates. Restriction of the intrahepatic circulation is an important predisposing cause of trophopathic hepatitis in man. It most commonly results from the swelling of liver cells previously injured by a toxicopathic agent. Pregnancy, vomiting and anorexia contribute to the development of a trophopathic hepatitis by reducing the amount of protective nutriment available to the liver cells. An increased metabolic rate may have the same effect by increasing the general bodily requirements for protein. It is also possible that certain poisons, such as selenium and trinitrotoluene, can produce the condition by combining with components of protein so as to render them inutilizable.

Estimation of 17-Ketosteroids in Urine in Diagnosis of Adrenal Tumors.—According to Callow and Crooke a high level of excretion of 17-ketosteroids in the urine is recognized as evidence of the presence of a secreting tumor of the adrenal cortex. This level is not an infallible guide. It was misleading in 2 cases. In a woman with basophilism associated with a carcinoma of the adrenal cortex the level was deceptively low, and in a girl with virilism without an adrenal tumor it was deceptively high. The authors report 14 cases with basophilism or virilism in which excretion of 17-ketosteroids was at the expected level. Of these 3 had tumors of the adrenal cortex; in the remaining 11, adrenal tumors had been suspected but were absent. Talbot attempted to increase the specificity of 17-ketosteroid estimation for diagnosis of adrenal tumor by determining the proportion of 3-beta-hydroxy-17-ketosteroids in the total fraction. The authors found that the 3-beta-hydroxy-17-ketosteroids formed about 10 per cent of the total for normal men, women or children, while in 2 girls with adrenal tumors the proportion was 50 per cent and 63 per cent 3-beta-hydroxy-17-ketosteroids. The authors think that Talbot's modification of the assay is promising and suggest that the isolation of dehydroisoandrosterone from urine or the finding of a high ratio of beta to alpha ketosteroids in urine is of fundamental importance in the diagnosis of tumors of the adrenal cortex.

Symptomatic Sprue in Lymphosarcomatosis of Small Intestine.—Fritzsche reports lymphosarcomatosis of the small intestine and of the mesenteric lymph nodes in a man aged 45. The diagnosis of endemic sprue was based on chronic fatty diarrhea, swelling of the abdomen, emaciation, mild anemia of secondary type and a roentgenologic study which demonstrated a severe jejunitis, ileitis and colitis. There were no signs of tetany, and the pigmentation was not abnormal. The very low blood pressure suggested adrenal insufficiency. There was little obstruction of the lacteals, but the disturbance in the absorption of fats could be explained by the extensive lesions of the intestinal mucosa and of the mesenteric lymph nodes. The necropsy revealed extensive lymphosarcomatosis of the small intestine, particularly of the jejunum and of the upper portion of the ileum (lymphoblastic type of lymphosarcoma). There were numerous lymphosarcomatous nodules with superficial and penetrating ulcerations. Erosion of the smaller vessels was noted in some of the nodules. There was considerable effusion of blood into the intestine. The sarcomatous process involved the retroperitoneal, pancreaticoduodenal, periaortic left ileac, inguinal, the upper cervical and the right peritracal lymph nodes. Ascites was not excessive. There was a severe subchronic inflammation of the small intestine, particularly of the jejunum and of the upper portion of the ileum. Death occurred within five months after the occurrence of the first symptoms. The rapid course may be responsible for the absence of abnormal pigmentation and tetany. Osteoporosis was not noted on clinical examination and the necropsy. Its absence may be explained by the fact that pathogenic changes of calcium metabolism deficiency need not be present because of considerable amounts of calcium being stored in the bones. Roentgenologic examination revealed alterations in the small intestine. Microscopic postmortem studies revealed lymphosarcomatous tissue in the lymph nodes. The diagnosis of endemic sprue should be based

not alone on symptoms but also on pathologic and etiologic data. The sprue syndrome may be present in cases of malignant disease of the small intestine and lymph nodes in which the involvement is extensive; i. e., in cases in which the functional impairment of the lymph stream interferes considerably with the absorption of fats.

Hereditary Transmission of Cancer.—Hanhart reports a study of descendants of 121 married couples in which both partners had cancer. A total number of 590 children sprang from these marriages, 359 of whom lived to be over 40 years of age, 286 over 50 and 188 over 60. Only 30 of the 121 couples had children who developed cancer. The total number of the children was 43, 26 men and 17 women. Two of them developed cancer in their forties, 3 in their fifties, 11 in their sixties and 27 in their seventies. Except for a few, all died from cancer. Only one seventh of the 188 children who lived to their seventies and both of whose parents suffered from cancer developed cancer likewise, whereas six sevenths of the persons did not at the age at which the hazard of cancer is greatest in Switzerland. The average age to which both partners of the 121 parents attained was 66 years. The average age of the 30 couples whose children developed cancer was 68 years. The average age to which their children with cancer lived was 61 years. It cannot be concluded from this limited material that the descendants may develop cancer at an earlier age than their parents. A single case may occasionally be significant in some other direction. Two children, a son of 65 and a daughter of 60 years, were in good health although their father had primary multiple malignant epitheliomas and their mother died from cancer of the uterus. The series of 121 married couples with cancer represented the incidence in the canton of Glarus. The average cancer expectancy of their 286 children when past 50 years of age amounted to around 13 per cent, whereas cancer expectancy of the population of the city of Zurich (about 320,000 people) was about 20 per cent. Both partners of the 33 out of the 121 married couples developed cancer of the stomach, and only 11 per cent of their children did likewise. Thus Julius Bauer's concept of a special predisposition of certain organs to cancer was not demonstrated. The results of this study are much like those of investigations on twins. They suggest absence of a specific hereditary predisposition to cancer.

Intrasternal Blood Transfusion.—Naegeli emphasizes advantages of intrasternal transfusions in the treatment of patients in whom no suitable veins for injections are available. The method is indicated in dehydration of various types as in many intestinal diseases whose incidence is high in wartime. Intrasternal infusion of human serum is the method of choice in severe burns with extensive skin lesions. Continuous intrasternal transfusion is preferable to intravenous drip in treating restless patients and patients with peritonitis. A patient with the needle in position may safely assume a lateral position and may eat. The method is contraindicated in any disease of the sternum and in aortic aneurysm. Introduction of a small amount of sterile fluid into the mediastinum by piercing the inner plate with the needle is not harmful. Amounts up to 1,000 cc. of human serum, or of sodium chloride solution (tutofusin), were given in one to one and a half hours with a 20 cc. syringe and in five to eight hours by a drip irrigator. The needle should be inserted in the middle of the sternum at the level of the second or third interspace. A mild pain felt by the patient when blood is aspirated offers a fair indication that the point of the needle has entered the bone marrow.

Clinical Indications of Sternal Puncture: Report of Acute Aleukemic Leukemia. M. F. Fernández and F. C. Otermin.—p. 69.

*Importance of Early Diagnosis of Leprosy. F. Contreras and J. Guillén.—p. 89.

Early Diagnosis of Leprosy.—Contreras and Guillén emphasize the importance of early diagnosis of leprosy because it is curable in the early stage. Leprosy is acquired only by direct or indirect contact. Children and young adults, especially those poorly nourished and living in unhygienic surroundings and having frequent contacts with leprosy patients, are the most frequent victims of the contagion. Enlargement of the inguinal

lymph nodes, induration of the cubital nerves, infiltration and slow depilation of the ends of the eyebrows, erythematous spots, symmetrical zones of anesthesia in certain areas on the limbs, hyperesthesia of the bones, chronic rhinitis and depilation of the armpits are the early signs of leprosy. The intracutaneous histamine test on a suspected leprosy spot gives a positive result, which consists of lack of peripheral erythema about the punctured spot, slow formation of a wheal, absence of local itching and rapid disappearance of the papule. *Lepra bacilli* are found in the nasal mucus with or without reactivation of the disease with potassium iodide (3 Gm. daily up to production of nasal catarrh) in the blood and in the secretions such as urine, semen and milk and from the cutaneous lesions. In pure nervous leprosy the bacillus can be found by a biopsy of an enlarged subcutaneous nerve.

*Diagnosis of Carbon Disulfide Poisoning. Rodenacker.—p. 828.

Diagnosis of Carbon Disulfide Poisoning.—Rodenacker states that the industrial use of carbon disulfide has greatly increased in connection with the artificial silk and related industries but that carbon disulfide poisoning is relatively rare. It occurs chiefly in connection with breakdown of equipment and with new installations. If the carbon disulfide content of inspired air exceeds 0.15 to 0.2 mg. per liter of air, acute and more or less delirious mental disturbances may result. Some men who have been exposed to carbon disulfide may go to a physician and tell of their fear of mental derangement, others may attack their co-workers, still others may take to nocturnal prowling or to irresponsible ranting and destruction. The author thinks that the derangement of the brain function is the result of the impairment of the organic lipoids in the tissues about the infundibulum by the fat dissolving carbon disulfide. This impairment subsides rapidly, for after three weeks the mental equilibrium is usually restored. The carbon disulfide delirium is accompanied by considerable loss in weight, probably as a result of damage to the metabolic centers in the midbrain, but this loss is also rapidly compensated during convalescence. Impairment of libido and of sexual potency also results from carbon disulfide poisoning. The diagnosis can be further corroborated by determining the carbon disulfide content of the air in the work shop. If it exceeds 0.2 mg. per liter, the xanthogenate determination of the blood and fluctuations in the weight will help to decide the diagnosis. The author also directs attention to the carbon disulfide neuritides. The nerves of the lower extremities, particularly the peroneal nerve, may become paralyzed, but these lesions likewise have a favorable prognosis. Carbon disulfide may also cause neuritis of the optic nerve with amblyopia. This form of amblyopia has a better prognosis than amblyopia caused by lead, arsenic or tobacco. Carbon disulfide may also cause colics, which are brought on by pylorospasm.

Encephalitis Association with Trichinosis. Elisabeth Pohlmann.—p. 769.

*Complement Fixation Reaction with New Pig Antigen in Trichinosis. A. Gaase.—p. 761.

Complement Fixation Reaction with New Pig Antigen in Trichinosis.—Gaase reports results of complement fixation reaction with an antigen from the muscles of trichinosis pigs. The serums of 5 patients with the clinical diagnosis of trichinosis gave slightly positive or even negative results with rat antigen, but 100 per cent positive results were obtained with pig antigen. The pig antigen proved superior to the rat antigen. It is suggested that the pig antigen is closer than the rat antigen to the parasite causing trichinosis in man.

Book Notices

Inadequate Diets and Nutritional Deficiencies in the United States: Their Prevalence and Significance. Report of the Committee on Diagnosis and Pathology of Nutritional Deficiencies, Food and Nutrition Board, H. D. Kruse, Chairman. Bulletin of the National Research Council, Number 109, November 1943. Paper Pp 56 Washington, D. C.: The National Research Council, National Academy of Sciences, [n. d.].

This booklet represents an exhaustive piece of work by the Committee on Diagnosis and Pathology of the Food and Nutrition Board. There is brought together in this report all the available literature as well as much unpublished material concerning appraisal of the nutritional status of the population of this country. A much better perspective of this problem can be obtained from a survey of the reports so assembled. From the recorded data it can be seen that by whatever standard nutrition is judged there is widespread consumption of diets below the recommended levels. Numerous figures in tables and text of the report substantiate this fact. Studies made in the thirties as well as those in the past three years indicate that in the lower income groups only 20 to 30 per cent were receiving adequate diets. In the later studies the percentages of individuals in various levels of society who did not receive the recommended amounts of the various essential nutrients was surprisingly high. As a rule the inadequacies were found in the fruits and vegetables more frequently than in protein foods.

The result of these poor diets is found in the incidence of deficiency states. In the past recognition has been limited to the acute types of deficiencies, which are in the minority. With the means at hand today to recognize chronic, gradually developing states by refined chemical and clinical examinations, the prevalence of such conditions is found greater than has ever been suspected. The importance of these latent, chronic deficiencies to the health of a nation is shown by numerous quoted studies in which low levels of nutrition were found to have an undesirable effect on body states and functions.

This report serves the useful purpose of demonstrating the extent of nutritional deficiencies by sheer weight of evidence. It should serve to correct the opinion sometimes expressed that the extent of nutritional deficiencies is exaggerated. In the conclusion attention is drawn to the fact that our goal should not be just passable health but buoyant health. This objective can be more readily obtained by the practical application of the knowledge of nutrition which is being developed so rapidly rather than by indifference to these facts. Certain steps which might be taken to insure a better understanding of deficiency states are outlined.

A Provisional Classification of Diseases and Injuries for Use in Compiling Morbidity Statistics by The Committee on Hospital Morbidity Statistics. Medical Research Council Special Report Series No. 248. Boards. Price, 3s. Pp. 168. London: His Majesty's Stationery Office, 1944.

This special report accentuates what appears to be a fundamental conflict of purpose in the classification of diseases and injuries. The main interest of biometricians in classification lies in statistical summarizations based on diagnoses made either during life or after death from a wide variety of sources. For them disease or death lists are desirable which will allow ready grouping and from which conclusions of material statistical significance can be drawn regarding the incidence of disease, the causes of death and other information based on mass compilations. The clinician, on the other hand, wishes a classification of disease which will allow accuracy, completeness, and reasonable uniformity; it should be acknowledged that the individual clinician's diagnosis provides the source from which the biometrician works.

The Provisional Classification of Diseases and Injuries under discussion does not appear to recognize these issues clearly. It has drawn extensively from the International List of Causes of Death, from the Diagnosis Code of the United States Public Health Service and from English sources, on the one hand, and from the clinical classification of the Standard Nomenclature of Disease and the Standard Nomenclature of Operations, on the other. The resultant classification with code numbers lends itself better to the statistical purpose than it does to the clinical. Neoplasms, for example, are classified as to whether they are

malignant or nonmalignant and as to general location; but it is impossible to specify the more detailed location or nature of the tumor in most instances. As a clinician's classification, therefore, this is unsatisfactory. Indeed, that fact is pointed out in the preface in a somewhat equivocal manner: "It is not suggested that it [the provisional classification] should replace the Standard Nomenclature of Disease of the American Medical Association in those hospitals in which the latter has been adopted, and which have a record system justifying the use of that more detailed nomenclature." In spite of this statement it may be feared that the greater simplicity of this list will appeal to some physicians and will cause them to feel that more refined diagnoses are not necessary.

There are several features of disease classification which may be emphasized: 1. It is not feasible to employ exactly the same type of classification of causes of death as it is for diseases; e. g., many diseases of the skin never cause death. 2. There is a difference 'in' purpose between classifications of disease as desired by the biometrician and by the clinician. 3. The principal problem of the classification of diseases and causes of death is how the needs of both groups can be satisfied. 4. The importance of this entire problem would justify an international conference when one becomes possible. Conferences of this type have been held periodically to revise the International List of Causes of Death. It may be advisable and feasible to enlarge the next such conference to include discussions of the wider subject.

An Atlas of Anatomy. By J. C. Boileau Grant, M.C., M.B., Ch.B., Professor of Anatomy in the University of Toronto. In Two Volumes. Volume II: Vertebral and Vertebral Column, Thorax, Head and Neck. Cloth. Price, \$5. Pp. 205-390, with 233 illustrations. Baltimore: William Wood & Company, 1943.

Professor Grant deserves thanks and congratulations for the production of an excellent atlas which undoubtedly will be of great service to medical students and clinicians. The second volume follows the general plan of the first, illustrating the vertebral column, the thorax, the neck and the head. The section on the vertebral column is relatively large and well done, and so the atlas will be welcomed by orthopedists and clinicians though less attention is given to muscles than in most works of this kind. This volume contains 233 drawings, of which 38 are diagrams, thus bringing the total for the two volumes up to 460. This number is about half that for Spalteholz's atlas and one third that for Toldt's atlas. But since the drawings are regional instead of systematic, more is represented in fewer plates. The regional plan accords well with the accelerated program now followed in the medical schools, under which there is not time for the old leisurely but effective method of repeated dissections.

The halftone illustrations are excellent. They are drawn by Mrs. Chubb, a former pupil of Max Broedel, on the basis of photographs of special dissections, and so may be relied on for accuracy. Under each drawing appears a list of points to be especially observed. These "observations" add much to the value of the plates. Slight variations from the normal and minor defects, such as are found in nearly every cadaver, are faithfully represented and the "observations" draw attention to them.

Each volume has its own index for convenient reference.

The atlas can be recommended to both medical students and practitioners.

Safe Convey: The Expectant Mother's Handbook. By William J. Carrington, A.B., M.D., F.A.C.S., Attending Gynecologist, Atlantic City Hospital, Atlantic City. Cloth. Price, \$2.50. Pp. 256. Philadelphia & New York: J. B. Lippincott Company, 1944.

The author has written a long book for the expectant mother, and the book does not appear well balanced. There is too much scientific material which the lay person cannot appreciate, such as discussion of calories, grams, milligrams and micrograms. The electrocardiogram, fluoroscope, x-rays, percentage of hemoglobin, renal function tests and many other laboratory procedures are discussed in a manner likely to bewilder the lay person. The author discusses the Caldwell and Molloy classification of pelvis, mechanism of labor, ovulation and fertilization. Two pages are devoted to a discussion of insulin. He states that in World War I a lack of vitamins led to the final surrender of the Germans; that vitamin E tends to prevent mis-

carriage. Positive proof has not to date been advanced supporting the relationship between abortion in the human being and lack of vitamin E. Formulas for feeding the baby and various diseases of the baby over the first year or more of life are described. Certain misstatements also are made, for example, the author states that in the bitterling test for pregnancy the fish menstruates; that Jane Seymour, third wife of Henry VIII, was delivered by cesarean section and survived. There is no proof that she had such an operation, and she died in the puerperium. Much of the scientific data could have been omitted and in future editions the author should check some of the questionable statements of fact.

Pharmacology. By Michael G. Mullins, M.D., A.B., A.M., Associate Professor of Pharmacology, College of Physicians and Surgeons, Columbia University, New York. With a foreword by Charles C. Lieb, A.B., M.D., Hoesack Professor of Pharmacology, College of Physicians and Surgeons, Columbia University. Oxford Medical Outline Series. Cloth. Price, \$4. Pp. 482. New York, London & Toronto: Oxford University Press, 1944.

This is not a textbook of pharmacology in the ordinary sense, since the author has followed rigidly the apparent intention of the publishers to have an outline of pharmacology. The volume is one of the Medical Outline Series. In presenting subject matter in this form the author gives his material in a manner which many times is not completely satisfactory, since an outline does not provide any opportunity for discussion of controversial subjects. There is considerable strain at times in applying the outline method, and frequently statements are made which are quite dogmatic and even trite, as for example on page 346:

D. Pharmacology of the Heart.

1. The heart acts as a pump.
 - a. It propels the blood from the venous into the arterial side.
 - b. It maintains a "normal" or adequate blood pressure.

In spite of the restrictions offered by the method of presentation, the author has been able to present pharmacology from the modern therapeutic approach, even to including forms of therapy other than the use of drugs. This point of view would make the book much more acceptable to the practicing physician than the old type of pharmacology textbooks. The author should be commended for completely casting aside the old apothecary system and using only the metric system throughout the book. Revision of the manuscript has apparently taken place up to the time of going to the press, because information on new drugs is available in this book.

Obstetric Cases. By D. MacMillan, Obstetrical and Gynaecological Surgeon, Christchurch Hospital, New Zealand. First Series. Cloth. Pp. 142. Christchurch, New Zealand: N. M. Peryer Limited, 1943.

This book is a compilation of thirty-one obstetric cases, most of which illustrate the mechanism of labor, the dystocia which resulted from abnormalities of this mechanism, and the manner in which the author treated these patients, but a wide variety of obstetric complications are reported. Among them are abdominal pregnancy, abruptio placentae, contracted pelvis, contraction ring, prolapse of the cord, eclampsia, failed forceps and placenta previa. In many instances the author recounts analogous cases reported by Robert Lee more than a hundred years ago. The first part of the book deals with training in obstetrics, rules in practice, causes of maternal and fetal mortality, signs of fetal distress and antepartum examinations. The conservative suggestions and pithy remarks of the author make the volume interesting and instructive.

Psychosomatic Diagnosis. By Flanders Dunbar, M.D., M.D.Sc.D., Ph.D. With foreword by Leonard G. Rowntree, Colonel, Medical Reserve Corps, United States Army. Cloth. Price, \$7.50. Pp. 741. New York & London: Paul B. Hoeber, Inc., 1943.

The author is one of the leaders of investigation and progress in the field of psychosomatic medicine, having begun her work in this field at Columbia University some twelve years ago. Essentially psychosomatic medicine involves the codification of certain technics of medical practice that have prevailed since the beginning of time and the inclusion within this practice of some of the dynamic aspects of Freudian technic. The work provides information on the taking of the history of a case, with special reference to factors in the field of psychosomatic medicine. The provision of actual examples of the use of the technic

in investigating cases makes the book especially useful. Special chapters are devoted to fractures, cardiovascular disease, coronary occlusion and rheumatic conditions. There are also several chapters concerned with contrasting profiles, personality profiles and conditions in which overlapping occurs. A useful bibliography and index complete the volume.

On the Influence of Trades, Professions, and Occupations in the United States, in the Production of Disease, 1837. By Benjamin W. McCready, M.D. With an introductory essay by Genevieve Miller, M.A. Boards. Price, \$1.75. Pp. 129, with portrait. Baltimore: Johns Hopkins Press, 1943.

In 1835 the Medical Society of the State of New York proposed as a subject for one of its annual prize essays "the influence of trades, professions and occupations in the United States in the production of disease." Benjamin W. McCready, M.D., of New York was declared the winner. His sixty page essay was published in the Transactions of the Medical Society of New York. Recently it was reprinted in book form. There had not been much consideration given to this subject in the United States up to this time, owing largely to the fact that industries were small and rather indefinite in nature. While McCready did give consideration to specific hazards and diseases of thirty-one employments, he dwelt largely on the sociological aspects, as improper housing, intemperance in laborers and exploitation of workers. The essay gives a remarkable insight into the conditions of labor and living in that period, many of which have been improved now by legislation and general elevation of standards of living. It was undoubtedly a realistic approach to the problem of occupational disease and presents a sharp contrast to present methods in this field, which has become greatly enlarged and defined.

Physical Foundations of Radiology. By Otto Glasser, Ph.D., Professor of Biophysics and Head of Department of Biophysics, Cleveland Clinic Foundation, Cleveland, Ohio, Edith H. Quimby, Sc.D., Associate Professor of Radiology (Physics), College of Physicians and Surgeons, Columbia University, New York, Lauriston S. Taylor, Ph.D., Chief of X-Ray Section, National Bureau of Standards, Washington, D. C., and J. L. Weatherwax, M.A., Philadelphia General Hospital and Graduate School of Medicine, University of Pennsylvania, Philadelphia. Fabricated. Price, \$5. Pp. 426, with 95 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

A knowledge of radiologic physics is a necessity for every physician who intends to use x-rays and radium as a therapeutic means. Such knowledge is of great aid in acquiring a familiarity with the technical use of the x-rays for diagnostic purposes. The authors of this book are leaders in their specialties and considered as constituting a court of appeals in questions relating to the physical aspects of roentgen diagnosis and roentgen and radium therapeutics. The chapters are well balanced. The information is offered in attractive form which should be understandable without difficulty by every physician. This book can be recommended highly to every one who practices or prescribes radiology.

Eat to Live: The Blue Book of Cooking. By Eula Bee Corban, Esther Robertson Hallock, and Mabel Martin. Cloth. Price, \$1.75. Pp. 140, with illustrations. New York: M. S. Mill Co., Inc., 1943.

This book of recipes is planned primarily for a period when many of the substances usually available in the diet are lacking, so that ingenuity and knowledge are necessary in planning diets. About 150 recipes are included in the book. Its most useful special feature, however, is the diagrammatic exemplification of the amount of essential ingredients contained in one portion of the dishes when eaten. This graphic formula shows, for example, that fluffy frosting on an 8 inch square cake provides a very small modicum of calories and nothing else.

Sexual Anomalies and Perversions: Physical and Psychological Development and Treatment. A Summary of the Works of the Late Professor Dr. Magnus Hirschfeld, President of the World League for Sexual Reform. Compiled as a Humble Memorial by His Pupils. A Textbook for Students, Psychologists, Criminologists, Probation Officers, Judges, and Educationists. [Authorized Translation.] Cloth. Price, \$4.95. Pp. 650. New York: Emerson Books, Inc.; London: Francis Aldor Publisher, 1944.

This is a reprint of the work published in England. Magnus Hirschfeld died some years ago. He made many contributions to the literature of sexology. The present work is a bare outline and hardly to be considered at this time either a learned or a modern contribution to the field concerned.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BRONCHIAL ASTHMA AND BRONCHIECTASIS

To the Editor:—What is the proper treatment of an asthmatic patient who has a complicating bronchiectasis? The patient, a married woman aged 28, has had asthma for years. It is at present in a severe form almost all the time. She was sent to me for x-ray treatment for the asthma because of recent favorable reports. I gave her a total of 1,000 roentgens, using high voltage therapy in divided doses. There seemed to be slight improvement. Examination with iodized oil revealed a bilateral cylindrical bronchiectasis; this included both bases. X-ray examinations of the sinuses are negative. The only other positive finding is a palpable thyroid. She has no symptoms of hyperthyroidism. I have not had a basal metabolic test made as yet. What do you think is the proper disposition of this patient? Do you think the bronchiectasis is causing the asthma or vice versa?

R. Nelson Long, M.D., Selma, Ala.

ANSWER:—Adequate treatment of a patient who has both bronchial asthma and bronchiectasis is usually impossible, although much can be done to lessen the symptoms. It is known that bronchiectasis does not cause bronchial asthma. It is believed, although this has not been proved, that bronchial asthma may in some cases lead to bronchiectasis. The two conditions coexist rather frequently, but most patients with asthma do not develop bronchiectasis and the latter can occur without asthma. Bullen, Chobot, Selby, Raia and Viswanathan have emphasized the frequency of the association of the two illnesses and have pointed out that bronchial infection and obstruction are important etiologic factors. Watson and Kibler in Arizona found that in 90 per cent of their patients with bronchiectasis allergy was also present as shown by the history, positive skin tests, associated allergic conditions and the presence of at least 10 per cent eosinophils in the nasal or bronchial secretions. Because asthmatic patients frequently move to Arizona, their figures, while accurate for their patients, are probably much higher than occur in the practice of physicians in other localities.

Treatment, in order of preference, includes (1) antiallergic measures, (2) general hygienic treatment, (3) postural drainage, (4) bronchoscopic aspirations and (5) lobectomy. Antiallergic measures should be carried out as thoroughly as possible. A complete allergic survey should be made, including scratch and intradermal skin tests; all suspected allergens should be removed, and if they cannot be avoided, e. g. house dust, injections of extracts of these substances should be given with a view to raising the patient's resistance (hyposensitization). General hygienic measures include adequate diet and rest, administration of vitamins and removal of definite foci of infection. Respiratory vaccines and avoidance of cold, damp climates may be of some service. Postural drainage should be used in all cases and over a long period of time. Bronchoscopic aspirations assist in the removal of sticky sputum and thereby help both the asthma and the bronchiectasis, but relief is only temporary.

In recent years lobectomy or even pneumonectomy has given excellent results in selected cases, according to Cole and Nalls, Head and others. Given a fairly good risk, a good chest surgeon and a unilateral bronchiectasis, surgery seems definitely indicated; all other measures can give only temporary and partial relief. Unfortunately, in this case, lobectomy is more hazardous because the condition is bilateral.

Instillations of iodized oil are essential for the diagnosis of bronchiectasis. Therapeutically, however, the procedure has been widely criticized. Results have not been too good even in the hands of the most enthusiastic workers. Opponents of the procedure have shown that untoward reactions are not infrequent: allergic reactions to iodine or poppyseed, circulatory failure, spread of infection, damage to lung tissue, spontaneous pneumothorax, massive collapse and even fatality. Most men who have tried the procedure have abandoned its use.

TESTESTERONE PROPIONATE FOR ELDERLY MAN

To the Editor:—I have been giving testosterone propionate to a patient over 60 years old for the last year, 10 mg. intramuscularly twice weekly, mostly for the purpose of stimulation and sedation. What I should like to know is this: Is there any danger in continuing to give it to him in this amount? It is believed that the prolonged administration of gonadotropic hormones may predispose to cancer formation, but if I am correct this applies only if they are used locally but not by injection. I would appreciate it if you would verify whether I am correct or not, as these injections are rather beneficial to the patient.

George Kalichman, M.D., Santa Monica, Calif.

ANSWER:—There may be confusion introduced by speaking of "stimulation and sedation." Testosterone propionate in adequate dose is a stimulant to the seminal vesicles, prostate and penis and to libido and potentia. Doses of 10 mg. intramuscularly twice weekly would cause such slight stimulation that an adult male would hardly be aware of it subjectively. In cases of climacteric syndrome testosterone propionate serves to reestablish autonomic nervous stability and in that sense is a sedative. The latter use is far more important in patients of the age referred to by the questioner. Such treatment may be continued for periods of months or several years if necessary to continue the relief from climacteric symptoms. It is not apt to be helpful if employed merely for the stimulation of libido and potentia, nor is such therapy considered wise by conservative physicians.

A further confusion is introduced by the questioner in referring to gonadotropic hormones, since testosterone is not gonadotropic. The term should be used to refer only to the pituitary or similar materials which stimulate the testes. Testosterone is a product of the testes. Gonadotropic hormones are not known to predispose to cancer formation. Whether testosterone does so predispose is debatable, but, since testosterone is a physiologic stimulant for the development of the prostate, ordinary clinical caution would dictate that it should be used only when there is clinical certainty that malignant disease is not present in the prostate. Furthermore, repeated prostatic examinations should be conducted throughout the course of therapy to be certain that no tumor appears. It is probable that the relationship between testosterone and tumor development in the genital tissues is not dependent on local application but is due to the physiologic effect which is obtained whether the material is taken by parenteral injection, local application or orally in the form of methyltestosterone.

SODIUM THIOSULFATE AND HYDROCHLORIC ACID SOLUTIONS FOR SCABIES

To the Editor:—Solutions containing sodium thiosulfate 20 per cent, mixed with hydrochloric acid 5 per cent, are applied to the skin at different intervals in the treatment of scabies. I understand this was used in World War I. Is this treatment feasible?

W. A. Newton, M.D., Beaumont, Texas.

ANSWER:—The treatment of scabies with a solution of sodium thiosulfate followed by weak hydrochloric acid solution is well established. According to Reuben Friedman (Scabies—Civil and Military, New York, Froben Press, 1941, p. 235) Crocker, in the 1905 edition of his textbook, reported the use of a solution of sodium hyposulfite 12 Gm., cologne water 32 cc. and rose water to make 256 cc. followed by a solution of tartaric acid 6 Gm. in 256 cc. of distilled water. Posen in 1929 used 40 per cent sodium thiosulfate (number 1) followed by 2.5 per cent hydrochloric acid (number 2). Number 1 was sponged on at night, number 2 the next morning. No complications were seen even in children. The itching ceased in three days, and the treatment ended after the sixth day.

Ravaut and Malhieu in 1934 reported the results of the use of the same strength of the thiosulfate but followed it with a somewhat stronger solution of the acid, 4 per cent, which was applied fifteen minutes after the first. The treatment was preceded by a soap and water bath, the skin was dried and the solutions were rubbed in over all the skin except the face and head. An hour later the same procedure was repeated. After the skin had dried, the patient dressed. On the second day the same four applications were made. On the third day a soap and water bath and fresh clothes were prescribed. Two days' treatment was usually enough, but a longer course can be used if necessary. They had perfect results with 52 patients, 11 of

them children, and with 15 patients who had been previously treated without success.

In 1936 Kulchar and Meininger (Sodium Thiosulfate in the Treatment of Scabies, *Arch. Dermat. & Syph.* 34:218 [Aug.] 1936) published a report on this method of treatment of 50 patients ranging in age from 7 months to 62 years. One week after the treatment was ended all were free from scabies; but 1 patient had a relapse or reinfection five weeks later, though free from symptoms for four weeks. Six patients repeated the treatment too often, but only 1 of them had a mild dermatitis, after the eighth application. This method gave better results than they obtained in a control series of 50 cases treated with the Danish ointment.

W. S. Parker ("Hypo-HCl" Treatment of Scabies, *Lancet* 1:987 [April 29] 1939) praises the method and says that it deserves wider use. Friedman used it with success.

Only A. E. Ingels (Scabies: Its Treatment with Benzoyl Benzoate as Compared with Sodium Thiosulfate plus Hydrochloric Acid, *California & West. Med.* 50:265 [April] 1939) has any criticism of the method. He used only one treatment a day, 40 per cent sodium thiosulfate rubbed in and allowed to dry, then 4 per cent hydrochloric acid rubbed in and allowed to dry. The next day this was repeated. The third day a bath was followed by clean clothes. The patients were warned not to repeat the treatment without permission of the doctor. Of 30 patients 4 were not cured and 5 showed mild dermatitis venenata. Many "complained of aggravated or distressing itchy sensations, which betrayed the peculiar tenacity characteristic of a sulfur dermatitis." Repetition of the course aggravated these symptoms, and 2 patients had severe dermatitis. He did not use the method in cases complicated by secondary infections or other skin manifestations. These caused more trouble than just described. He used benzoyl benzoate in a comparable series of cases and had less trouble and more constant cures from it.

Whatever the method, the success or lack of it depends largely on the intelligence of the patient and the care of the physician in describing the minutiae of the treatment. Carelessness in the clean-up at the end of the course is the chief cause of reinfection. Overuse of the remedy because of itching at the end of the ordinary course is the chief cause of dermatitis. The patient ascribes the itching to the activity of the mite instead of to the irritation of the remedy and adds to it by application of more of the remedy.

RENAL COMPLICATIONS OF NEWER SULFONAMIDES

To the Editor:—Is sulfadiazine more apt to produce kidney complications than sulfathiazole and, if so, how and why? Has any evidence accumulated in the literature that sulfamerazine is more dangerous in the same respect than sulfadiazine or sulfathiazole? Isn't it pretty generally recognized that the urine should always be alkalinized when any of these three drugs is being administered in therapeutic doses?

Preston S. Herring, M.D., Vicksburg, Miss.

ANSWER.—Precise statistical data comparing the incidence of renal complications in a large series of patients treated with sulfadiazine and sulfathiazole are not available. Yet in one large institution therapy with sulfathiazole was associated with kidney complications more frequently than with sulfadiazine. Likewise the incidence of renal dysfunction was greater with sulfathiazole than with sulfamerazine. Sulfamerazine did not appear to cause any more renal disturbances than sulfadiazine. There are at least three mechanisms whereby the kidneys are affected by the foregoing compounds. First, the drugs or their conjugated products may precipitate out of the urine, particularly in the tubules, and result in a suppression of the free flow of urine. This produces an oliguria and a retention of metabolites usually excreted by the kidney. Second, the compounds may exert a direct toxic effect on the renal parenchyma, provoking areas of focal necrosis with a secondary cellular reaction. Third, there is increasing evidence that the kidney may be the site of a hypersensitive type of reaction to the compounds or, as Rich terms it, an anaphylactic type of hypersensitivity. This type of vascular lesion does occur in other tissues of the body and is more readily produced by sulfathiazole than by sulfadiazine or sulfamerazine. It may be that this third mechanism accounts for the more frequent occurrence of renal lesions following therapy with sulfathiazole.

It is now generally recognized that attempts should be made to have patients excrete an alkaline urine when any one of the three drugs is utilized in therapeutic doses. It should be emphasized that the urine should be alkaline throughout the twenty-four hour period, which may require divided doses of a large amount of alkali such as sodium bicarbonate. In addition to alkalinization of the urine the fluid intake should be of that magnitude which will insure in an adult the output of a liter or more of urine in twenty-four hours.

HAY FEVER FROM TREE POLLENS

To the Editor:—Can you tell me of any desert or mountain resorts that are free of oak, hackberry, elm, box elder, mimosa, acacia and ash trees? My wife has hay fever badly from pollen of these trees during April and May and since desensitization treatments have not helped her much so far I should like to send her away.

M.D., Virginia

ANSWER.—While the overlapping natural ranges of the eight trees mentioned with their numerous related genera and species cover all of the United States and Canada, it is possible that there are a number of places where the victim could be comfortable during April and May. The greatest difficulty with the desert resorts is the possible presence of elms and box elders, particularly the latter, which are widely used for shade in dry areas. The difficulty in the mountain resorts is the possible presence of ash and oak. Much of the Southwest, from west Texas to southern California, must be avoided because of acacia, mimosa or the closely related mesquite. There are all too few year round pollen records in the mountain and desert areas. Miami, Fla., might be satisfactory as far as air borne pollens of the types mentioned are concerned. While hackberry and oak are listed for the district, the oaks finish their pollination before April, and hackberry pollen was not encountered during the year tests were made. Key West would be even better than Miami. The only possible difficulty in southern Florida would be the presence of royal poinciana, which is rather closely related to mimosa and acacia. However, this type of pollen is not wind borne and was not detected in the air in the pollen studies made at Miami.

COUNTING, STAINING AND PRESERVATION OF SPERMATOZOA

To the Editor:—I should like to know the method used to count the number of spermatozoa per cubic centimeter of semen. Can the spermatozoa be stained? How are they preserved? What is the best temperature to use in order to keep them alive over the necessary period of time?

Joseph T. Nardo, M.D., Somerville, Tenn.

ANSWER.—The technic used is the same as for making a leukocyte count. After the seminal fluid has liquefied, which usually occurs within ten minutes, it is measured in cubic centimeters. A sample is drawn up to the 0.5 mark in the white pipet. A solution containing 1 per cent solution of formaldehyde U. S. P. diluted 1:10 and 5 per cent sodium bicarbonate in distilled water is then drawn up to the 11 mark. The dilution is 1:20. A drop of the diluted seminal fluid is allowed to flow under the cover glass of the counting chamber. After allowing a few minutes for settling, one counts all the spermatozoa in the four large squares (each one 1 mm. square and 1 mm. deep), using the high dry objective. The total number of spermatozoa counted is then multiplied by 20 (for dilution), divided by 4, multiplied by 10 (for cubic millimeters, since the depth of the cells is 0.1 mm.) and by 1,000 for cubic centimeters. The result obtained is the number of spermatozoa in 1 cc. To obtain the total number of spermatozoa ejaculated, the number in 1 cc. of seminal fluid is multiplied by the volume of seminal fluid.

Many different methods have been developed to stain spermatozoa. Two methods can be found in the following references:

Greenberg, B. E.; Berman, S.; Gargill, S. L., and Griffin, R. C.: A New Method for Staining Spermatozoa, *J. Clin. Endocrinol.* 3:119 (March) 1943.

Cuyler, W. K., and Baptist, Margaret: A Spermatozoal Stain for Clinical Studies, *ibid.* 2:571 (Sept.) 1942.

The semen is best preserved in a refrigerator under ordinary ice box temperature. The addition of a small crystal of thymol will keep it in a suitable condition for a week or so.

SULFONAMIDES IN PRODROMAL STAGE OF MEASLES

To the Editor:—Is it advisable to use sulfonamides in the catarrhal stage of measles before the appearance of Koplik spots or the rash? Will the administration of sulfonamides given in such a case delay the appearance of the rash?

M.D., New York

ANSWER.—There is no objection to using sulfonamides in the catarrhal stage of measles before the appearance of the rash. Some physicians believe that complications are diminished by such a procedure. In one large experience a delay in the development of the rash because of the treatment described has not been observed.

EVOLUTION IN MEDICINE

ERNEST E. IRONS, M.D.
CHICAGO

As we view the accomplishments of the medical departments of the Army and Navy thus far in the war, we are moved with pride in their achievements. To those of us whom time has robbed of the opportunity of again participating in uniform, this creditable performance is a source of deep satisfaction and no little envy. The medical officers today have the advantage of almost thirty years of better professional education, better technical knowledge and methods and, with these, better mechanical appliances and transportation.

It may be of interest to note at this time the course of development of medicine which has led to this great advance in treatment and cure of wounds and disease to see how these observations may apply to the future progress of medical education and practice.

The history of medicine of any period is the history of contemporary economic, social and political conditions. Medicine prospers in discovery and improvement along with other branches of science, and in turn these discoveries reflect similar progress or regression in the social and political life of the times. The social and economic problems encountered in the practice of medicine are not peculiar to medicine and cannot be solved by medicine alone. Bad housing and bad nutrition contribute directly to bad health, but they arise not through any fault of medicine but from bad economic and social situations. And so their cure is to be sought not through a radical change in medical procedure but rather in the remedying of social ills, in which effort medicine will gladly participate. The cure of many a sociologic-medical problem is a grocery order rather than a prescription.

EVOLUTION IN MEDICINE

The advances in medicine as in all science have been achieved as the result of slow accumulation of knowledge. What appears to be a sudden startling discovery in medicine is usually rather the culmination of long patient work in several sometimes distantly related fields. Some small new fact perhaps brings the many elements into focus, and a valuable new method emerges. Vesalius is credited with making the first clinical diagnosis of aortic aneurysm. His enviable accomplishment consisted, however, in recognizing the similarity of the pulsation beneath the shoulder blade of the nobleman

Welserus to the pulsation in aneurysms of peripheral vessels, which had been recognized and described by Hippocrates nineteen centuries before. In recent times the discovery of sulfanilamide was conditioned by preceding and apparently unrelated studies on the physiology and growth requirements of bacteria; Fleming's observations on the limitation of growth of bacteria by contaminating mold depended on experiments on the nutrition of bacteria and the effects of diffusible substances unfavorable to their growth; out of these concepts came penicillin.

Medical education began in Europe in the monasteries, then was fostered in the universities; its growth was hindered by superstition and obstructed by laws based on tradition; its tempo of growth became more and more rapid until the present time. The twentieth century has been marked in this country by reforms in the method and content of medical education and the close affiliation of medicine with ancillary science. With this marvelous advance has come a corresponding reduction in mortality from disease and a notable increase in life expectancy. The improvements in medical education and increase in medical knowledge in the past forty years are directly reflected in the increased efficiency of medical care of our military sick and wounded. The whole story of medicine in this country is that of an orderly evolution unrestricted by regimentation or federal interference.

We are now faced with certain proposals which would alter the conditions of medical practice as a part of a larger plan ultimately to revise our entire social and governmental structure. While it is intended here to refer only to the medical aspects of this proposal, it must be recognized that medicine which deals with the health of the people touches closely on their economic and social standards.

History is full of examples of the close interrelation of medicine and social, economic and political life of peoples. Many of our present day problems are merely repetitions in modern setting of identical situations of ancient civilizations. Haskell has reviewed the growth and course of Roman civilization from the founding of Rome, through the Republic, to the fall of the Empire, the establishment of a totalitarian state and finally total disintegration. He has pointed out the remarkable similarity of problems of that period to our own.

It is significant that those who then advocated measures of relief were motivated in part by desire to improve things and in part to satisfy what they conceived to be their personal advantage. Then and now measures of cure of medical as well as of economic

and political illness need to be scrutinized not only as to motive and proposed mechanism but also as to their ultimate affect on medicine or on the state of the future. The Roman Catiline, who in general has been given a bad name, himself espoused the cause of the oppressed masses. He had suffered irritating defeats and injuries; he explained his course by saying "I have undertaken, as is my wont, the public cause of the distressed." But his program had no regard for results beyond the immediate gain or loss of his campaign for consul. When asked as to this, he said "If a fire is lighted against me, I shall put it out not by water but by pulling down the roof of things."

Among the social reformers and political propagandists who would force wide governmental and social changes by an oblique attack on medicine there are too many Catilines who would pull down the roof of medicine in order to carry out other plans looking to a totalitarian state. We shall hope not to be obliged to say, as did Tacitus concerning Roman intellectual life, that "genius died by the same blow that ended public liberty."

We are urged to consider the alleged advantages of socialized medicine under bureaucratic control as provided in several countries elsewhere in the world. But we are concerned with the system of medical care in the United States and not with that of other countries. We must not try to tell them what to do or how to manage their medical economy nor, contrariwise, can we assume that a medical plan which fits their political and economic status would be good for us. Economic, political and social ideals determine the course of all activities in nations just as they do in villages and neighborhoods. These ideals differ, and a medical program will take the pattern of the thought and desires of a people.

Individualization is necessary in dealing with the diverse economic and social conditions in the several portions of this country. Measures in recognition of this evident fact will go far to solve social and medical injustices which unavoidably result from economic privation and inequality. Here in America the central thought of our life and development has been freedom of action—free enterprise. There are now those who would attempt to impose a regulation of medicine as the first step toward a totalitarian system in a nation whose ideology revolts at such a change. They would make the change largely on the ground that there have been instances in our present system in which selfishness has prevented the successful operation of free enterprise and that there have been injustices in the operation of our social system. That there have been such injustices is true: no plan short of a Utopia is perfect, and there is great probability that the rules of Utopia would need revision with changing times.

Medicine along with our entire social thinking is undergoing change for the better, but this orderly though sometimes lagging change of evolution is far different from the change promoted by revolution, with the destruction of standards built up by decades of laborious and idealistic effort.

Certain lay persons and a few doctors blithely recommend socialized medicine, apparently without full knowledge of the inevitable results entailed in its operation.

When it fails they will move on to other fields, along with other irresponsible advocates of unsound economic programs, leaving the wreckage behind. Some of them are well meaning and may be said to be contemporaneously sincere; others are motivated by more sinister aims which threaten the very roots of our republic.

SOCIAL SERVICE

There is a group of sincere social workers who are rightly impressed with the social and medical difficulties of the poor and ignorant and are anxious to assist in their relief. They properly take pride in the social gains already achieved among many groups of unfortunates, but in their desire to extend rapidly this beneficent action they naively seize on socialized medicine as a vehicle. They fail to see that by bringing medicine down to an average level they would sweep away many of the standards they themselves have already set up. If there is one activity which requires as much as does medicine the utmost individualization, it is that of the social worker. Her work is based on the sensible solution of each peculiar problem and can never be brought successfully into the regimentation of socialized medicine.

There are many groups of sufferers who as yet have not been reached, but the destruction of present standards and the lowering of the average of the entire group to the level of years ago is a poor way to approach an already difficult problem. It is this destruction of present standards both medical and social that is one of the most vicious features of socialized medicine. Social service, which has accomplished much in the alleviation of distress, should have a care to distinguish between real and false friends.

There are still others who masquerade under the cloak of social service whose purpose is not to improve the lot of the poor but rather to use social service and medicine as a stalking horse to attack the present economic and social régime and set up a bureaucracy entirely foreign to the ideology of America. In their arguments they condemn the medical profession as selfish and obstructive and with superficial sophistries urge a system that they themselves know will not accomplish the ends they outwardly propose.

The falsity of the charge that medicine has done nothing to provide better medical service to the public is evident on reference to the record. This record is enviable but, by reason of its cautious development, lacks dramatic appeal. By utilizing the scientific method this progress has been sound and will endure. To plunge into a revolutionary plan with a specious appeal to the uniformed would be as disastrous to the general welfare as was planned food scarcity and the slaughter of little pigs.

Voluntary insurance against the costs of hospitalization was first broached seriously in the United States some twenty years ago. Today by gradual evolution of the so-called Blue Cross and similar hospitalization plans more than 15,000,000 Americans are insured against this hazard. However, even the Blue Cross hospitalization plan, as in effect today, is far different from the hospitalization plan first proposed. In the course of development of such plans it has been found necessary to protect the hospitals against the abuse of those who

would exploit the hospital as a place for a vacation. It has also been necessary to protect certain highly specialized medical services against exploitation by the hospital and by the patient. Likewise it has been necessary to protect the patient against exploitation by the hospital or by some of the specialistic technical medical services. In the gradual evolution of hospitalization insurance these safeguards have been developed.

More than twenty years ago there were available in the United States individual insurance policies which protected the policyholder against the costs of sickness, surgical operations and hospitalization. The rates for such insurance were prohibitive to all except a few. With the development, however, of more experience, permitting the accumulation of actuarial data, the large insurance companies of the United States have found it possible to develop group insurance against the costs of hospitalization, disability due to illness, surgical and obstetric fees and medical care at rates so reasonable that today more than 18,000 American industries are covered with a total of 20,000,000 policyholders. Within five years one insurance company has written such insurance for 2,700 industrial groups covering 1,650,000 persons; another company has covered 1,500,000 in 2,300 industries, and the numbers are growing daily.

Why could not this have been done before? In addition to the necessary evolution of public knowledge and opinion and of actuarial data, medicine itself had to progress in effectiveness so that an insurance policy might be financially possible to the man of limited means and at the same time be actuarially sound. Hospitals themselves had to become available. In 1900 there were 1,000 hospitals in this country; today there are over 7,000. Methods of medical care had to be improved so that hospital days of illness could be reduced to a workable number.

In 1912 the average hospital stay for appendicitis was eighteen days; now it is eleven days. The average course of lobar pneumonia has been reduced from weeks to days. The case fatality of epidemic meningitis in 1910 was 80 per cent; in 1935 30 per cent; today it is 5 per cent. These are only examples of the general improvement in the quality and effectiveness of medical care, which in turn makes possible readjustment of insurance rates to the point at which they are within the reach of the average worker on a sound actuarial basis.

Finally there are the plans which gradually have been developed by state and county medical societies, including today several plans which now cover tens of thousands of policyholders. All of these plans are recognized as still evolutionary and subject to improvement. It is the traditional American system to develop safe technics by cooperative experimental methods by the people who serve and by those who are served. By the exercise of private initiative with recognition of the right of the individual state and of the federal government to regulate so as to insure actuarial safety, we shall be able to develop in the United States plans so that all workers and their families may be protected by a technic that is still sufficiently American to grant freedom of choice to the worker and to the employer

and eliminate any excuse for the intervention of governmental bureaucracy.

The care of the indigent has for many decades been willingly accepted by physicians, and suitable institutions have been created usually under state and local community direction supported by the state and community by taxation and by private funds. The indigent share with others the improvements and advances in medical care, but it is noted that the plans for socialized medicine give scant attention to this group, from whom but little political advantage can be gained.
